Dr. Abhay Kulkarni, Hon. Secy. IIIE Aurangabad Chapter
Dr. Sachin K. Patil, RIT, Rajaramnagar, Sangli
Dr. Akshay A. Pujara, GEC, Ahmedabad

Director's Message

I am very much delighted to note that Department of Mechanical Engineering of Sardar Vallabhbhai National Institute of Technology (SVNIT) Surat is organizing *4th International Conference on Industrial Engineering (ICIE 2017)* which is scheduled to be held during December 21-23, 2017. This conference is organized in association with *Indian Institute of Industrial Engineering (IIIE), National Headquarters, Mumbai.*

ICIE 2017 is concerned with most recent development in the field of industrial engineering. The present three-day conference is designed to provide a common platform to the experts and delegates to share their experiences, research ideas and discuss various related issues and challenges. The event will provide an international technical forum for academicians, researchers, industry, organizational leaders, government and non-government representatives, management consultants and service providers to meet and exchange new ideas and present their findings of on-going research in various areas of industrial engineering.

The organizers have carefully selected four keynote lectures by experts from University and Industry along with over 240 technical papers by researchers in 37 parallel sessions. A slot is arranged for a panel discussion.

I am sure that the technical papers of the conference will provide a unique opportunity to rapidly disseminate research results that are of timely interest to the engineering fraternity. I warmly welcome all the participants and wish you all to have very fruitful technical sessions.

My hearty congratulations to the organizers of ICIE 2017 for organizing the event so well and convey my best wishes for the success of the conference.

Prof. S. R. Gandhi
Director

December 9, 2017

Head of Department's Message

I am happy to note that the Department of Mechanical Engineering of Sardar Vallabhbhai National Institute of Technology (SVNIT) Surat is organizing *4th International conference on Industrial Engineering (ICIE 2017)* in association with *Indian Institute of Industrial Engineering (IIIE), National Headquarters, Mumbai*, which is scheduled to be held during December 21-23, 2017.

Industrial Engineering is the one of important specialization of Mechanical Engineering. It deals with the design, improvement, and installation of integrated systems (as of people, materials, and energy) in industry. I suppose that the ICIE 2017 will bring academic, scientists, leading engineers, industry researchers and scholar students to exchange and share their experiences and research results about all aspects of Industrial Engineering, and discuss the practical challenges encountered and the solutions adopted.

The Department of Mechanical Engineering was established since the inception of college (1961). The department offers an undergraduate, five post graduate courses and Ph.D. programme in all the disciplines of Mechanical Engineering. The department has at present around 40 faculties and more than 1000 student. Apart from regular teaching, the department is actively engaged in testing, consultancy, and research and development services to support various industries in and around Surat.

I would like to welcome all the participants in Department of Mechanical Engineering. The departmental laboratories are open for visit during the working hours.

I give best wishes for the success of the conference.

December 09, 2017

Prof. K. P. Desai
Head of Department

IIIE Director General's Message

I am pleased to note that the Department of Mechanical Engineering of Sardar Vallabhbhai National Institute of Technology (SVNIT) Surat in collaboration with Indian Institution of industrial engineering Mumbai (IIIE) is organizing 4th International conference on Industrial Engineering (ICIE 2017), which is quite important and relevant theme for the Indian Industries and academia in global context.

Industrial engineering has evolved over the last century, constantly moving into new applications and industries using new tools—while never leaving its traditional industries. This Conference is aimed at discussing the emancipating dimensions of industrial engineering discipline, which has made progress during the last few decades. The industrial engineer (IE) has long concerned the profession because the term industrial may have been defined too narrowly. There may be other words starting with the letter

ICIE 2017 is a platform to bring researchers and experts from academia and industry on a common platform for discussing the latest technologies and managerial tools being adopted in the field of Science, Technology and Management. It will help to provide an opportunity for all branches of industries, to disseminate the information on most recent and relevant research, theories and practices in the area of Industrial Engineering.

I am sure that large number of distinguished speakers and delegates attending this conference would endeavor to deliberate on innovative ideas, contributing from their rich experience, in depth knowledge and success.

Organizing this type of conferences requires great amount of vision, leadership and dedication. I compliment SVNIT Surat and IIIE Mumbai for achieving this successfully.

My warm greetings to the distinguished speakers, delegates and all participants!

December 09, 2017

Dr. Bhaskar M. Bhandarkar
Chairman, IIIE

Message from the President IIIE Surat Chapter

I am greatly delighted that the Mechanical Engineering Department of SVNIT Surat in association with Indian Institution of Industrial Engineering (IIIE) has done marvellous work in organizing the ICIE-2017 scheduled during December 21-23, 2017.

Industrial engineering has evolved over the last century, constantly moving into new applications and industries using new tools—while never leaving its traditional industries. This Conference is aimed at discussing the emancipating dimensions of industrial engineering discipline, which has made progress during the last few decades. The industrial engineer (IE) has long concerned the profession because the term industrial may have been defined too narrowly. There may be other words starting with the letter

'I' that better capture the diversity of industrial engineering, including innovation, information, integration, implementation, instruction, involvement, and intrapreneur. Therefore, this Conference tries to expand the focus of the industrial engineering profession by recognizing that the *'I'* in IE may stand for many more things than the traditional term, *Industrial*.

I understand that around 250 papers will be presented in 37 technical sessions in this conference and delegates will be participating from various organizations. In summary, I can proclaim here that our industrial engineering professionals from academia, industry, government and service sector etc. have become responsive to the society's needs, have been adept at creating or advancing new technical tools and have advanced the knowledge frontiers of industrial and systems engineering discipline. I am having confidence that the participants of this conference will make productive efforts to transfer, disseminate and communicate the new and ever expanding dimensions of Industrial Engineering.

I congratulate specifically to Dr. Tushar N. Desai and Dr. Ravi Kant and many others for their continuous and sustained efforts in making the conference a successful one. I also convey my best wishes to the delegates, faculty members and other associates for their valued contributions to ICIE-2017.

Atik M. Desai

Chairman, IIIE Surat Chapter and
Vice President - Chief Administrative Officer
Larsen & Toubro Limited
Central Services, Hazira Manufacturing Complex

Message from the President SVNIT Alumni Association – Surat Chapter

It is pleasure to note that Department of Mechanical Engineering is organizing 4th International Conference on Industrial Engineering (ICIE 2017) during 21st to 23rd December, 2017. We are delighted to be part of this prestigious technical event.

SVNIT ALUMNI ASSOCIATION – SURAT CHAPTER is the first registered chapter of the SVNIT ALUMNI ASSOCIATION. One of the main objectives of local alumni chapter is to promote and encourage sharing of technical information and knowledge for betterment of students and professional fraternity. Over last two years, the chapter has organized more than 20 events for alumni-students-faculty-staff of SVNIT. It includes technical seminars, cultural events, support/sponsorship of conference and other social events related to well being and life style, spirituality, yoga, blood donation, medical camp, etc. All these have been possible due to support of more than 225 local alumni members and faculty/staff of SVNIT.

I take this opportunity to thank distinguish alumnus Er. Bhadresh Shah, who is also the founder President of SVNIT ALUMNI ASSOCIATION for his contribution in supporting this noble cause. With his contribution to our local alumni chapter, this is the fourth technical conference that we are supporting/sponsoring for SVNIT. We shall further look forward to jointly support similar technical events for other departments in future.

I appreciate the efforts of Dr. Ravi Kant and Dr. Tushar N. Desai; organizing secretary of ICIE 2017 for their dedicated and sincere efforts in organizing this conference. I wish grand success to this technical event and hope that it will meet expectations of participants as well the organizers.

Nilesh Shah
President
SVNIT AA - SURAT CHAPTER

Message from the Conference Organizing Secretaries

Dr. Ravi Kant

Dr. Tushar N. Desai

The 4th International Conference on Industrial Engineering (ICIE 2017) is scheduled to be held during December 21-23, 2017. ICIE 2017 is a platform to bring researchers and experts from academia and industry on a common platform for discussing the latest technologies and managerial tools being adopted in the field of Science, Technology and Management. It will help to provide an opportunity for all branches of industries, to disseminate the information on most recent and relevant research, theories and practices in the area of Industrial Engineering.

There has been overwhelming response to the call for papers from the researchers, academicians of the leading institutes and organizations all over the world. The papers present theoretical research results and application case studies. Around 300 delegates will be attending the conference which consists of 4 keynote speeches and 37 Parallel Sessions. They range from mathematical modeling and simulation to industrial applications and management.

We would like to thank the reviewers and members of international advisory committee, faculty members of the department of mechanical engineering for their assistance and seriousness. We are very grateful to all authors and session chairs for contributing actively in this conference. We should acknowledge the student volunteers for their assistance.

We are extremely thankful to Larson and Toubro (L&T) Hazira, Surat, SVNIT Alumni Association, Surat Chapter and Swapn Preeti Bhadrash Shah Foundation, Surat, for extending their financial support to ICIE 2017. We are also thankful to 'Indian Institute of Industrial Engineering (IIIE)', National Headquarters, Mumbai for extending their valuable support to the conference.

We are extremely thankful to Dr. S. R. Gandhi, Director of our institute for their constant support and encouragement in making this international conference a success. We are also thankful to the Deans, Head of Departments, Hostel section and Estate section for various support required time to time.

We are also thankful to our Research Scholar Mr. Himanshu Prajapati, Ms. Shruti J. Raval, Ms. Umangi Pathak, Mr. Sachin Agarwal, Mr. Javed Malek, Mr. Pranay Parmar, Mr. Ashish Patel, Mr. Puneet Kumar and M. Tech. Students Mr. Sandeep Mani Tripathi, Mr. Mitesh Kumar Dabhi, Mr. Chintan Chaudhari, Mr. Venkatesh Burela and Mr. Mayank Soni for their efforts in bringing up this conference.

Engineering and Management, Nagpur, Maharashtra, India

Abstract: Cost estimation is the need of the every industry. Time driven activity based costing (TDABC) has gained the lot of attention for accurate cost estimation. But, implementation of costing system requires investment in time and money. Further, small scale industries (SSI) have constrained on the uses of various resources such as time and money. Therefore, the aim of the paper is to understand the suitability of TDABC for SSI. This research examines suitability from the in-depth literature review and the survey. The study finds that, TDABC is suitable to SSI. But, future research is required by SSI. Because. Most of the studies were carried out in medium and large scale industries.

Keywords: TDABC, Time driven activity based costing, SSI, Review, Survey, Suitability

1. INTRODUCTION

In this Era of intense global competition on price and quality of products, there is a need of accurate cost information. The continual search for a better costing system ushered in the activity based costing (ABC). ABC was first designed for manufacturing processes (Wegmann, 2010). Using ABC can lead to classifying activities as value-added and non-value-added and allow for elimination of the non-value-added activities (Gunasekaran and Sarhadi, 1998). Therefore, ABC is a cost accounting system from the perspective of operational process. But, Kaplan and Anderson (2003) have suggested that many large organizations abandoned their ABC project because of rising cost and employee irritation. Then they proposed time driven activity based costing (TDABC) which is evolved from ABC. TDABC requires only two parameters i.e. unit cost of supplying capacity and time required to perform an activity (Demeere, Stouthuysen and Roodhooft, 2009). Time required to perform an activity is estimated using time equations.

The aim of the paper is to discuss the suitability of TDABC for small scale industry in India. The paper initially discusses the concept of TDABC followed by its evolution. Then the literature review of is discussed. Thereafter, the results of the survey are discussed. Finally, the suitability of TDABC is discussed for small scale manufacturing industry.

2. EVOLUTION OF TDABC

Earlier, in the eighties, traditional costing was used. In this system, indirect costs are distributed over product costs based on single or a few volume based cost drivers. While the direct cost is directly assigned to product cost.

Therefore, traditional costing system is suitable in stable environment with less or fixed indirect costs and with a small variation in activities, products or services (Cooper and Kaplan, 1988; Tse and Gong, 2009). But over a period, with the increasing manufacturing complexity, the traditional costing system was not able to produce accurate costing. Therefore, to determine accurate and reliable costing and to provide managerial reports ABC was developed.

According to Hilton (2005), “ABC is a two stage procedure used to assign the overhead cost to products and services produced”. In the first stage, activity cost is determined. In the second stage, product cost is determined by allocating activity cost based on the product’s consumption. But, because of employee irritation and high maintenance cost, many industries abandoned their ABC model (Kaplan and Anderson, 2003). So, a new simpler TDABC approach is developed, which is based on existing ABC model.

TDABC model simplifies ABC by elimination difficulties in implementation. It reduces the work of interviewing and polling staff to assign resources to activities. This model assigns resources cost directly to the products. TDABC requires only two sets of estimations. First, it calculates the cost of supplying resource capacity. Second, it calculates capacity rate.

3. CONCEPT OF TDABC

Kaplan and Anderson (2003) have introduced TDABC to overcome difficulties in traditional ABC. This method identifies the capacity of each department or process and allocates the cost of this capacity of resource groups over the cost object based on the time required to perform an activity (de Arbuló et al., 2012). Like ABC, TDABC is also

a two step process as shown in Fig. 1; in first step overhead cost is assigned to activity and in second step activity cost is assigned to product or service. In this process TDABC requires only two parameters. First parameter is unit cost of supplying capacity. Where unit cost is calculated using equation 1

$$\text{Unit cost} = \frac{\text{Cost of capacity supplied}}{\text{Practical capacity of resources supplied}} \quad (1)$$

Second parameter is consumption of capacity (unit times) by the activities the organization performs for products, services, and customers. The consumption of capacity by an activity is generally measured in terms of time. It is calculated by an equation 2, which is also called as time equation. A time equation is an equation that describes the time to perform an activity as a function of several drivers.

$$\text{Time required each time the activity} = \beta_0 + \sum \beta_i \cdot X_i \quad (2)$$

Where

β_0 is the standard time to perform the basic activity,
 β_i is the time for each incremental activity,
 X_i is the quantity of each incremental activity

Demeere, Stouthuysen and Roodhooft (2009) and Stouthuysen et al. (2010) have given the following steps for implementing TDABC. The complete process is shown in Fig. 1

- Identify the various activities (resource groups, departments)
- Estimate the total cost of each activities
- Estimate the practical capacity of each resource group
- Calculate the unit cost of each activity
- Determine the time required each time the activity is performed
- Multiply the unit cost of each activity by the time estimate for the event.

Fig. 1. TDABC Schematic (Everaert et al., 2008)

4. REVIEW OF TDABC

Many researchers conducted the case studies of TDABC implementation at different industries. These case studies are related to pig production, casting manufacturing,

electronic product manufacturing, wooden toys manufacturing, bicycle manufacturing, auto part manufacturing and precision casting factory. All these companies are medium or large scale in nature. The detail of these case studies is presented in

TABLE .

TABLE 1: Case studies on TDABC

Author	Type of industry	Remarks
(Bryon et al., 2008)	pig production	- TDABC can be used for guiding management with the decision problem of switching to batch farrowing in pig production - TDABC is useful to quantify both the economic and ecological impacts of a strategic decision
(Öker and Adigüzel, 2010)	casting manufacturing company	- TDABC model is more appropriate and easier for service companies to implement than manufacturing companies. - TDABC provides more relevant information about capacity utilization than standard costing and product profitability - Difficult to implement TDABC in manufacturing companies because the capacities are measured in terms of labor time, and some time it is difficult to measure capacity in terms of labor time
(Stout and Propri, 2011)	electronics company	Updating TDABC model is easier than ABC
(de Arbulo et al., 2012)	auto parts manufacturer	- TDABC is easier to use than ABC and traditional full costing in multiproduct/multi-process companies. - TDABC can capture the cost of the different products in the product mix. - TDABC calculates the cost of a product accurately, whereas Value Stream Costing (VSC) gives just an average value. But data collection for TDABC is complex
(Kachitvichyanukul, Luong and Pitakaso, 2012)	precision casting factory	The results of TDABC provide valuable information to managers for reducing waste in their business endeavors
(Monroy, Nasiri and Peláez, 2014)		- TDABC covers both product and process levels for decision making. - TDABC is not adapted to Generally Accepted Accounting Principles (GAAP) and companies that are using these systems should have another system generating reports for external uses
(Pongwasit And Chompu-Inwai, 2016)	manufactures wooden toys	- TDABC is more accurate and determine the appropriate prices of the products. - They found that TDABC identifies the production cost was consistent with the actual use of resources at the study company
(Siguenza Guzman et al., 2013)	.	Difficult to measure the time, the homogeneity and its maintenance
(Chiarini, 2014)		Difficult to implement because of time equations
(Kowsari, 2013)		If time is measured by inexperienced person, and if wrong time is considered for an activity then cost price allocated to activities will be unreliable

The researches have opined that TDABC provides more relevant information for capacity utilization, is used for quantifying economical and ecological impact, can capture the cost of different products in product mix, and is more easier than traditional costing more particularly ABC. But, most of the problems are related with the time estimation and formulation of time equation.

4.1 Advantages of TDABC

From the evaluation of TDABC system, many industries have implemented TDABC. Benefits of TDABC mentioned by different authors in manufacturing sector are given in TABLE

TABLE 2: Advantages of TDABC

Reference	Conclusion
(Bryon et al., 2008)	1) Guide managers with the decision problem 2) Allow to derive trade-offs between economic and ecological criteria
(Korpinen, Mochan and Uusitalo, 2010)	1) Assist management in strategic decision making 2) Enable a sensitivity analysis of production 3) Accurate, applicable and effective model
(Öker and Adigüzel, 2010)	1) It provides more relevant information about capacity utilization than standard costing and product profitability
(Stout and Propri, 2011)	1) Updation in the model more easier than in ABC. 2) TDABC is implemented with the support of ERP
(de Arbulo et al., 2012)	1) Capture the costs of the different products in the product mix 2) Analyze how capacity is being used
(Monroy, Nasiri and Peláez, 2014)	1) TD-ABC covers both product and process levels for decision making
(Mortaji, Bagherpour and Mazdeh, 2013)	1) TDABC is quick and easy costing method for determining the “Whale curve” of customer profitability and a natural complement to the balanced scorecard
(Pongwasit and Chompu-Inwai, 2016)	1) costing is more consistent with the actual use of resources
(Wouters and Stecher, 2017)	1) TDABC avoids grouping resources into cost pools, and so it has far fewer linkages that need to be updated 2) TDABC is flexible system.

Above discussion indicates that TDABC is a useful tool for managers and decision makers because it provides detailed and hierarchical decomposition of the cost.

4.2 Limitations of TDABC

Like every system TDABC is also having some limitations as given in TABLE

TABLE 3: Limitations of TDABC

Reference	Limitation
(Wegmann and Nozile, 2008)	1) TDABC is only useful for standard processes such as chain management supplying, some standardized production processes and consulting activities, call centers, hospitals, etc.
(Sherratt, 2005)	1) TDABC is limited to predetermined routines and activities
(Gervais, Levant and Ducrocq, 2010)	1) If staff reports their times when it is not possible to observe them directly then accuracy is debatable
(de Arbulo et al., 2012)	1) Collect data for TDABC seems to be complex
(Siguenza Guzman et al., 2013)	1) Over time it is difficult to measure the time, the homogeneity and its maintenance. 2) Estimating time for non-continuous or unpredictable activities is difficult

Reference	Limitation
(Mortaji, Bagherpour and Mazdeh, 2013)	1) Deviation in practical capacity and the required time for each activity may mislead managers into making inappropriate decisions
(Chiarini, 2014)	1) The drawback of the use of time equations is a deep and difficult analysis of all the activities and their internal transactions 2) Practical capacity is not that easy to calculate; often it is an approximation. However, at the same time, practical capacity needs to be accurate

The above limitations indicate the scope for improvement and area for further research. They are as follows.

- A continuous improving system can be developed so that cost for non routine activities can be determined.
- Instead of dependent on employees for data, continuous data recording system can be developed. Such continuous recording system will also solve the problem of estimating time for unproductive activities and it help to measure practical capacity.
- A methodology can be developed to simplify time equations and their analysis.

5. SURVEY

A survey on product costing was carried out by the authors to study the current practices in product costing in context of small scale furniture manufacturing industries in India. The aim of the survey was to determine:

- Which Costing method is used in the industry?
- What are the important aspects in costing process?
- How overhead are distributed over the product.
- What is the data recording system?

The survey was carried out in 25 industries. Industries having turnover less than 3 crore were selected for survey. A questioner was prepared (Appendix A) and personal interview was carried out.

5.1 Survey findings

When asked about costing technique used in their industry, none of them were able to answer. But during the discussion it was found that most of them were using traditional costing system, where as a few of them were using feature based costing system. The graphical representation of companies using different costing system is as shown in Fig. 2

To understand the importance of aspects of costing for the industries, The preference of aspects of costing process was asked. The result is shown in TABLE . It indicates that, small scale industries need fast and easy accurate system, which will be affordable to them. During the fourth and fifth question it is observed that, the overhead like water

consumption were neglected, whereas other overheads were added as percentage. The percentage of distribution was determined from the past experiences or in the proportion of last year. Some of the companies were electric cost as 2% to 3% of basic cost of product.

Fig. 2. Costing system used in small scale manufacturing industry

TABLE 4: Preference of aspects of costing process

Sr. No	Aspects of costing process	Preference
1	Accuracy of the estimate	1
2	Time taken to estimate & cost involved in costing process	2
3	Understanding of manufacturing process	3
4	Dependency of market data like material cost, operation rate	4
5	Complexity of calculations	5

When asked about the data collection system, it is observed that, 22% of the industries were having system or tool for data recording, which were in the organized sector, while remaining 78% were belongs to unorganized sector. It is represented graphically in the Fig. 3.

Fig. 3. Data recording system in industry

6. PROBLEMS IN SSI

In most of the countries, small scale industries (SSIs) are defined in terms of number of employees whereas in India, they are defined in terms of investment in plant and machinery (Singh, Garg and Deshmukh, 2010). In India, SSIs are defined as industries having investment in plant and machinery (excluding land & buildings) less than Rs 5 crore. Therefore costing system with low investment cost is a need of SSIs in India. Apart from this, in SSI, there are less employees. Therefore, one employee is handling many activities. Therefore, the capacity utilization of the machines and the activity is less. Hence, it is difficult to measure the practical capacity of the activity.

7. RESULTS AND DISCUSSIONS

The authors have conducted a survey at small scale manufacturing industries to understand, how cost estimation is carried out in industry. The cost estimators agreed on this during the interviews that, different cost estimators making similar estimates have different results because of the choice of the resource and method. Further discussion with cost estimators have indicated that, small scale industries in India don't have system to measure resources consumed in manufacturing. Based on this, following are the requirements of cost estimation technique for SSIs:-

7.1 Requirements of cost estimation techniques for SSI

Based on the literature and survey conducted by author following requirements of cost estimation techniques for small scale manufacturing industries are identified.

- A costing system should predict accurate cost of product.
- It should distribution of overheads should be in accordance with the way the resources are consumed.
- It should be able to measure unused capacities.

- It should determine the cost of each process or activity.
- Cost of small consumables like water should be considered in costing.
- Rejection cost of a product should be considered on the same product.
- Inefficient process and employee should be determined.
- Cost consuming activities should be identified.

7.2 Suitability of TDABC for Cost Estimation for SSI

From the literature discussed above, following features of TDABC makes it suitable for small scale manufacturing industry:-

- Provides the most accurate cost estimates
- Provides detailed cost structure
- Distributes the overhead in accordance with the way the resources are consumed
- Measures the unused capacities
- Determines the cost of each activity
- Easy to implement and easy to maintain
- Less cost of implementation
- Less data is required for cost estimation

8. CONCLUSION

Many researchers have attempted to implement TDABC in manufacturing industry. They pointed out the advantages and limitations in their respective studies. However, the aim of this paper was to understand the suitability of TDABC for SSI in India. Therefore, the detailed review of TDABC was carried out. Then the survey was conducted to study need of SSI were studied. The results and the discussion of the survey indicate that, TDABC is suitable to SSI in India. But, it was found that, most of the studies were written by creators of TDABC. Further it is observed that most of the studies were in medium or large scale industries. Hence future research is required by in manufacturing industries and especially in small scale industries.

Also, Organizations prefer to take actions to reduce the effects of the drivers instead of using them to allocate indirect cost. Hence the visibility to process efficiencies and capacity utilization is more important to them. Therefore, TDABC is more suitable to manufacturing industries.

SDJ International College, Vesu, Surat, Gujarat, INDIA

²Department of Applied Mathematics and Humanities,
Sardar Vallabhbhai National Institute of Technology, Ichchhanath, Surat, Gujarat, INDIA

Abstract:

Purpose – This paper aims to investigate the effect of demographic variables on attitude towards risk with respect to financial investment decision. The association between demographic variables and risk appetite for financial investment decision are also examined.

Design/Methodology/Approach – The structured questionnaire survey using multi-stage sampling method was conducted. The approximate sample size has targeted 735 investors of Surat City, India.

Findings – Ethnic groups do have significant impact on various aspects of financial investment decision. It has been also observed from the study that there is a significant association between ethnic groups and various aspects of financial investment decision such as awareness level towards financial avenues, types of portfolio, objectives for investment, risk associated with financial avenues and preference given to financial avenues for investment.

Originality/ Value – This research article will deliver the information about effect of investor's demographic characteristics. The article provides the scope for further hypothesis testing, development of new theories focusing relationship between demographic variables and risk appetite and its impact on financial investment demeanor. It will also be helpful to the researchers for further research in the area of consumer behavior for financial investment decision.

Keywords: consumer behavior, risk appetite, financial investment, ethnic groups

1. INTRODUCTION

Consumer behavior has always fascinated marketers all over the world. Rightly so, because it offers interesting insights into the working of the human mind in making purchasing decisions. The study of consumer behavior is a subjective topic. Hence, there are no absolutes. It was also found that the investor behavior is the process by which investor tends to satisfy his/her needs by showing their choices. The behavior of the investor can be affected by many of internal as well as external environment. The demographical factors play critical role in determining individual buying behavior for any goods or even services. Various studies have been conducted to identify investor buying behavior to identify how Investors are making financial planning to satisfy their future financial need. The income earning and income spending activities are a part of financial system (Prasad & Srinivas, 2012). It channelizes the savings of millions of small and retail investors into gigantic capital formation. Today, investors have large number of options available for investment i.e. Stock market, Bank F.D., Insurance (ULIPS), Mutual funds, PPF,

NSC, KVP, Real estate, Small medium enterprise, Agricultural product, Cottage industry, Bonds, Gold etc. All these financial instruments mobilize financial resources in the economy (Senthilkumar, Vijayabanu, & Nayagam, 2008).

Risk is an inherent feature of all types of financial investments due to the variability in the actual and expected returns on investment. The concept 'risk perception' means the way in which investors view the risk of financial assets, based on their concerns and experience. The attitude towards risk of investors is an important factor that influences the investment decisions. The risk-taking attitude determines the investment style (Bali et al., 2009; Fellner and Maciejovsky, 2007; Hunter and Kemp, 2004). An investor's psychology is one of the important factors that affect their perception about the market and attitude toward risk (Chang, 2008; Kourtidis et al., 2011; Young et al., 2012). Based on individual risk tolerance level, investors are classified into three categories: risk-averse, risk-neutral and risk-lovers. Demographic factors that have a significant impact on the investors' attitude towards risk include age,

gender, marital status, qualification, occupation, ethnic group, family type and level of income. Investors take risks according to their interpretation and perception which ultimately affect their behavior towards risky investment decisions.

Surat is India's 8th and Gujarat's 2nd largest city with the population of 4.5 million. Surat is also ranked 4th fastest growing cities in the Asia per capital. Among the highest income growing tax payer city in Asia in the year 2010-11 Surat contributed at 2200 crores to national exchequer. Surat is city with highest average annual household income. Surat is a standout. Surat has nearly the population size of a megacity; it is the youngest city in the entire group (with over 64% of the population below the age of 30); and the city's household income growth tops our urban universe by a comfortable margin. After adjusting for cost of living differences, Surat emerges as the leader in household income levels. The city is already a larger consumer market than Ahmedabad and Pune. The well developed commercial city of Gujarat, Surat has contributed a GDP of \$40 billion. The city is popularly known as the diamond capital of the world and the textile capital of India. In 2008, Surat was dubbed the wealthiest city of India in terms of per-capita income — at approximately equal to INR 4,57,671 according to a study jointly conducted by the National Council of Applied Economic Research's Rajesh Shukla and Future Capital Research's Roopa Purushothaman. Besides textile manufacturing, trade, diamond cutting and polishing industries, the city is also supported by intricate Zari works, chemical industries and the petrochemical and natural gas-based industries at Hazira, established by leading industry houses like Oil and Natural Gas Company Limited, Reliance Industries Limited, Essar Limited and Shell Limited (www.thesuniljain.com).

This research will take into account the effect of demographic variables on attitude towards risk with respect to financial investment decision. According to literature survey, individual's demographic characteristics have been proved to play a vital role in determine their risk taking attitude and in achieving financial goals. It has been stated that the demographic variables of investors and attitude towards risk are fully integrated into the consumer financial behavior. This research will support the belief that the influence of demographic variables on attitude towards risk regarding financial investment should not be ignored.

2. LITERATURE REVIEW

Park and Mahmood (2015) studied the impact of personality on risk tolerance and investment decisions. The purpose of the study was to investigate the relationship between risk-taking attitude, personality trait and investment decision among potential private investors in Kazakhstan, a post Soviet transition country. The authors

have adopted the quantitative research method. They have conducted the survey of students and teachers from a business school of Kazakhstan. The findings revealed that some of the personality traits has a significant positive effect whereas few have negative effect as well on the level of risk tolerance. The level of risk averse was differing with respect to gender and past investment experience. They also have found that level of risk tolerance have significant association with intention to invest in stock market. Based on the results they have suggested that investment advisor or agents should consider the personality trait and risk tolerance capacity while giving advice to private investors. (Park O. and Mahmood M., 2015)

Sindhu and Rajitha Kumar (2014) have studied the influence of risk perception of investors on investment decision. Their aim of research was to find the influence of risk perception on individual investors' investment decision particularly for mutual fund. The convenience sampling method were used to collect the response from investors of Kerala with used of structured questionnaire. The collected data were analyzed using various statistical tools like standard deviation, co-efficient of variance and simple regression analysis with the help of SPSS. Based on the analysis, the authors have concluded that investment decisions are very much influenced by investors' risk perception. Types of portfolio selection for financial investment have greater impact on risk perception. The investor preferred diversified portfolio than conservative portfolio to reduce the risk. They also have observed from the mean score analysis regarding risk perception of investors' that higher rate of return, the greater is its associated risk. (Sindhu K. P. and Rajitha Kumar S., 2014)

Shafi (2014) has studied the determinants influencing individual investor behavior in stock market. The aim of the author was to review the reported work to get the information and knowledge related to factors influencing investment behavior in different countries and their impact on risk tolerance and investment decision making process between men and women and among different age groups. The author has collected the various papers on determinants of investment behavior across the various different countries and prepared review paper. Thus, the researcher has adopted an exploratory study as a methodology. The conclusion revealed that there are number of elements which influence the individual investment behavior in stock market. It has been also found that some factors have enormous impact and other have little role to play in influencing individual investment behavior. The factors influencing individual investment behavior have been grouped into demographic, economic, social, psychological and uncommon in nature. The factors having a significant impact on individual investment behavior are age, gender, marital status, and confidence, irrational thinking, education, cognitive bias, past performance of the company,

risk factors, dividends, ownership structure, expected corporate earnings, accounting information and bonus payments. The uncommon factors found in various literature surveys conducted for different countries includes perceived ethics of the firm, stock marketability, publicity, inflation, expected losses in international financial markets, trading opportunity, diversification purpose, brand perception, control orientation, economic expectation and social responsibility which also have significant influence on individual investment decision.(Shafi, 2014)

Strydom and Metherell (2012) have conducted the research to find how demographic factors affect financial risk tolerance in a South African context. Stratified random sample was selected and binary logistic model was used to analyse the collected data to analyse the effect of independent demographic variables on financial risk tolerance level. Based on the analysis on the analysis, it was found that demographic characteristics of individuals play a significant role in establishing the level of risk tolerance. The major impact in determine the level of risk tolerance were played by age, income and gender. Whereas race and religion were not having significant influence on individual's subjective risk tolerance level. The authors also have observed that education did not affect level of risk tolerance significantly which is controversial to the various international evidence. It was also suggested based on results that marital status did not have much influence in establishing the individual's level of risk tolerance. (Strydom B. and Metherell C., 2012)

Anbar and Ekbar (2010) have conducted a study to investigate the relationship between different variables of financial risk tolerance and demographic characteristics. For analysis of data from 1100 university students, logistic regression, t-test and ANOVA analysis were sued. The analysis indicated that gender, department, working in job, monthly personal income, monthly family's total income and total net asset have significance in differentiating individuals into risk tolerance levels. But age, marital status and number of children have no significant effect on financial risk tolerance. The financial risk tolerance level of male students was higher than the female students. T-test have showed the result that financial risk tolerance level of student who are working in job were higher than non-working students. It has been also observed that there was a significant difference in risk tolerance level with respect to total monthly family's income and total net asset. Higher the family's total income, financial risk tolerance level were higher. Furthermore, lowest total net asset, the financial risk tolerance level was low. The results of the analysis supported the proposition about being effect of demographic variables on financial risk tolerance level.

Sung and Hanna (1997) have studied the factors related to risk tolerance. Their purpose of the study was to investigate the effects of individual characteristics and financial

variable on risk tolerance. They have chosen the 1992 Survey of Consumer Finances as their data set. Logistic regression analysis method was used to analysis their data set. They have found that difference in risk tolerance by gender, ethnic group, marital status and education could be due to difference in understanding regarding nature of risk. The result have shown that those who were more away from retirement have high risk tolerance than similar respondent whose expected retirement was closer. Ethnic group or race has significant influence on risk tolerance. The finding suggested that Non-Hispanic Whites had higher risk tolerance than Hispanic or those in other ethnic group than Blacks. Non-Hispanic Blacks had the lowest risk tolerance level. The authors also have observed that increased in predicted risk tolerance level with the increased in education level whereas, there were no significant difference noted among different occupations towards risk tolerance level. It was observed that there was significant impact of marital status and gender on risk tolerance level. The result showed those female headed households were lower risk tolerance level than male headed or married couples. (Sung J. and Hanna S., 1997)

3. RESEARCH METHODOLOGY

This study is exploratory and descriptive and is undertaken to understand the investors' behavior in the Surat city, India. The data has been collected from the homogenous sample that is the investors of Surat city, India. But again there has been heterogeneity among the investors as they fall into different ethnic groups. Data have been collected from various respondents through a structured questionnaire. Questionnaire contains rating scales and multiple choice questions. The target respondents have been requested to indicate their preference using a five scale likert scale. A sample survey has been conducted to estimate the population attributes by using a multi-stage sampling method using purposive sampling, convenient sampling and snowball sampling. The approximate sample size has been targeted 735 investors of Surat City, India.

Fig. 1. Conceptual framework of hypothesis

4. RESULT AND DISCUSSION

The data in this study were coded and tabulated. The data were analyzed with the help of SPSS package (IBM SPSS Statistics v22.0) which enabled data interpretation and making of statistical inferences.

Hypothesis –

H₀: The demographic variables of investors do not have an impact on risk appetite for financial investment decision.

H₁: The demographic variables of investors do have an impact on risk appetite for financial investment decision.

Profile of Investors –

Table 1 shows the demographic profile of investors.

TABLE 1: Profile of investors

Variables		No. of investors	Percentage
Gender	Male	550	74.8
	Female	185	25.2
	Total	735	100
Age	18-24	90	12.2
	25-34	182	24.8
	35-44	170	23.1
	45-54	160	21.8
	55-64	87	11.8
	65 & above	46	6.3
	Total	735	100
Marital Status	Single	132	18
	Married	582	79.2
	Divorced	5	0.7
	Widowed	12	1.6
	Separated	4	0.5
	Total	735	100
Qualification	Under Graduate	134	18.2
	Graduate	355	48.3
	Post Graduate	181	24.6
	Professional	42	5.7
	Others	23	3.1

	More than 400000	191	26
	Total	735	100

H_A- Gender and Risk Appetite for Financial Investment Decision

In order to know the association between gender and risk appetite for financial investment decision, the Pearson's chi-square test at 5% significant level has been carried out. Furthermore, to investigate the difference among gender towards risk appetite, the Mann-Whitney U test has been performed. For this purpose, the following null (H₀) hypothesis and alternative (H_A) hypothesis have been proposed.

H₀: There is no significant association between gender and risk appetite for financial investment decision.

H_A: There is a significant association between gender and risk appetite for financial investment decision.

Based on analysis performed with the help of SPSS, it is observed that calculated value of chi-square for risk appetite regarding financial investment decision is 38.207. The p values of these investment avenues at 5% significant level 0.000. As the calculated value of p is less than the critical value, so we could reject null hypothesis and conclude that there is a significant association between gender and risk appetite for financial investment decision.

H₀: There is no significant difference among gender towards risk appetite for financial investment decision

H_A: There is a significant difference among gender towards risk appetite for financial investment decision.

From the analysis performed with the help of SPSS, the p value of population median at 5% significant level of risk appetite for financial investment decision is 0.000. As p value is less than the critical value, so we reject null hypothesis, which means there is a significant difference among gender towards risk appetite for financial investment decision.

H_B- Age Groups and Risk Appetite for Financial Investment Decision

In order to know the association between age groups and risk appetite for financial investment decision, the Pearson's chi-square test at 5% significant level has been carried out. Furthermore, to investigate the difference among age groups towards risk appetite, the Kruskal Wallis test has been performed. For this purpose, the following null (H₀) hypothesis and alternative (H_A) hypothesis have been proposed.

H₀: There is no significant association between age groups and risk appetite for financial investment decision.

H_A: There is a significant association between age groups and risk appetite for financial investment decision.

Based on the analysis performed, it is observed that calculated value of chi-square for risk appetite regarding financial investment decision is 20.046. The p values of these investment avenues at 5% significant level 0.029. As the calculated value of p is less than the critical value, so we could reject null hypothesis and conclude that there is a significant association between age groups and risk appetite for financial investment decision.

H₀: There is no significant difference among age groups towards risk appetite for financial investment decision

H_A: There is a significant difference among age groups towards risk appetite for financial investment decision.

Based on the values found in the test, the p value of population median at 5% significant level of risk appetite for financial investment decision is 0.014. As p value is less than the critical value, so we reject null hypothesis, which means there is a significant difference among age groups towards risk appetite for financial investment decision.

H_C - Marital Status and Risk Appetite for Financial Investment Decision

In order to know the association between marital status and risk appetite for financial investment decision, the Pearson's chi-square test at 5% significant level has been carried out. Furthermore, to investigate the difference among marital status towards risk appetite, the Kruskal Wallis test has been performed. For this purpose, the following null (H₀) hypothesis and alternative (H_A) hypothesis have been proposed.

H₀: There is no significant association between marital status and risk appetite for financial investment decision.

H_A: There is a significant association between marital status and risk appetite for financial investment decision.

From the various test performed using SPSS, it is observed that calculated value of chi-square for risk appetite regarding financial investment decision is 9.494. The p values of these investment avenues at 5% significant level 0.302. As the calculated value of p is more than the critical value, so we fail to reject null hypothesis and conclude that there is no significant association between marital status and risk appetite for financial investment decision.

H₀: There is no significant difference among marital status towards risk appetite for financial investment decision

H_A: There is a significant difference among marital status towards risk appetite for financial investment decision.

Based on the Analysis, the p value of population median at 5% significant level of risk appetite for financial investment decision is 0.395. As p value is more than the critical value, so we fail to reject null hypothesis, which means there is no significant difference among marital status towards risk appetite for financial investment decision.

H_D - Qualification and Risk Appetite for Financial Investment Decision

In order to know the association between qualification and risk appetite for financial investment decision, the Pearson's chi-square test at 5% significant level has been carried out. Furthermore, to investigate the difference among qualification towards risk appetite, the Kruskal Wallis test has been performed. For this purpose, the

following null (H_0) hypothesis and alternative (H_A) hypothesis have been proposed.

H_0 : There is no significant association between qualification and risk appetite for financial investment decision.

H_A : There is a significant association between qualification and risk appetite for financial investment decision.

Based on the analysis performed using SPSS, it is observed that calculated value of chi-square for risk appetite regarding financial investment decision is 18.935. The p values of these investment avenues at 5% significant level 0.015. As the calculated value of p is less than the critical value, so we could reject null hypothesis and conclude that there is a significant association between qualification and risk appetite for financial investment decision.

H_0 : There is no significant difference among qualification towards risk appetite for financial investment decision

H_A : There is a significant difference among qualification towards risk appetite for financial investment decision.

Based on the value found from the test, the p value of population median at 5% significant level of risk appetite for financial investment decision is 0.039. As p value is less than the critical value, so we reject null hypothesis, which means there is a significant difference among qualification towards risk appetite for financial investment decision.

H_E - Occupation and Risk Appetite for Financial Investment Decision

In order to know the association between occupation and risk appetite for financial investment decision, the Pearson's chi-square test at 5% significant level has been carried out. Furthermore, to investigate the difference among occupation towards risk appetite, the Kruskal Wallis test has been performed. For this purpose, the following null (H_0) hypothesis and alternative (H_A) hypothesis have been proposed.

H_0 : There is no significant association between occupation and risk appetite for financial investment decision.

H_A : There is a significant association between occupation and risk appetite for financial investment decision.

From the value found in Pearson Chi-square test, it is observed that calculated value of chi-square for risk appetite regarding financial investment decision is 28.617. The p values of these investment avenues at 5% significant level 0.001. As the calculated value of p is less than the critical value, so we could reject null hypothesis and conclude that there is a significant association between occupation and risk appetite for financial investment decision.

H_0 : There is no significant difference among occupation towards risk appetite for financial investment decision

H_A : There is a significant difference among occupation towards risk appetite for financial investment decision.

As per analysis run through SPSS, the p value of population median at 5% significant level of risk appetite for financial investment decision is 0.000. As p value is less than the critical value, so we reject null hypothesis, which means there is a significant difference among occupation towards risk appetite for financial investment decision.

H_F - Ethnic Group and Risk Appetite for Financial Investment Decision

In order to know the association between ethnic groups and risk appetite for financial investment decision, the Pearson's chi-square test at 5% significant level has been carried out. Furthermore, to investigate the difference among ethnic groups towards risk appetite, the Kruskal Wallis test has been performed. To examine the weighted mean for each risk taking level for financial investment decision, the mean score analysis has been calculated. For this purpose, the following null (H_0) hypothesis and alternative (H_A) hypothesis have been proposed.

H_0 : There is no significant association between ethnic groups and risk appetite for financial investment decision.

H_A : There is a significant association between ethnic groups and risk appetite for financial investment decision.

Based on the analysis run using SPSS, it is observed that calculated value of chi-square for risk appetite regarding financial investment decision is 9.009. The p values of these investment avenues at 5% significant level 0.173. As the calculated value of p is more than the critical value, so we could fail to reject null hypothesis and conclude that there is no significant association between ethnic groups and risk appetite for financial investment decision.

H_0 : There is no significant difference among ethnic groups towards risk appetite for financial investment decision

H_A : There is a significant difference among ethnic groups towards risk appetite for financial investment decision.

As per analysis run through SPSS, the p value of population median at 5% significant level of risk appetite for financial investment decision is 0.203. As p value is more than the critical value, so we fail to reject null hypothesis, which means there is no significant difference among different ethnic groups towards risk appetite for financial investment decision.

H_G - Family Type and Risk Appetite for Financial Investment Decision

In order to know the association between family type and risk appetite for financial investment decision, the Pearson's chi-square test at 5% significant level has been carried out. Furthermore, to investigate the difference among family type towards risk appetite, the Kruskal Wallis test has been performed. For this purpose, the following null (H_0) hypothesis and alternative (H_A) hypothesis have been proposed.

H_0 : There is no significant association between family type and risk appetite for financial investment decision.

H_A : There is a significant association between family type and risk appetite for financial investment decision.

Based on the analysis using SPSS, it is observed that calculated value of chi-square for risk appetite regarding financial investment decision is 4.674. The p values of these investment avenues at 5% significant level 0.322. As the calculated value of p is more than the critical value, so we could fail to reject null hypothesis and conclude that there is no significant association between family type and risk appetite for financial investment decision.

H_0 : There is no significant difference among family type towards risk appetite for financial investment decision

H_A : There is a significant difference among family type towards risk appetite for financial investment decision.

From the various test run using SPSS, the p value of population median at 5% significant level of risk appetite for financial investment decision is 0.429. As p value is more than the critical value, so we fail to reject null hypothesis, which means there is no significant difference among family type towards risk appetite for financial investment decision.

H_H - Family Income (Yearly) and Risk Appetite for Financial Investment Decision

In order to know the association between family income (yearly) and risk appetite for financial investment decision, the Pearson's chi-square test at 5% significant level has been carried out. Furthermore, to investigate the difference among family income (yearly) towards risk appetite, the Kruskal Wallis test has been performed. For this purpose, the following null (H_0) hypothesis and alternative (H_A) hypothesis have been proposed.

H_0 : There is no significant association between family income and risk appetite for financial investment decision.

H_A : There is a significant association between family income and risk appetite for financial investment decision.

Based on the Pearson Chi-square test performed using SPSS, it is observed that calculated value of chi-square for risk appetite regarding financial investment decision is

32.383. The p values of these investment avenues at 5% significant level 0.000. As the calculated value of p is less than the critical value, so we could reject null hypothesis and conclude that there is a significant association between family income and risk appetite for financial investment decision.

H_0 : There is no significant difference among family income towards risk appetite for financial investment decision

H_A : There is a significant difference among family income towards risk appetite for financial investment decision.

Based on the values found in the test, the p value of population median at 5% significant level of risk appetite for financial investment decision is 0.007. As p value is less than the critical value, so we reject null hypothesis, which means there is a significant difference among family income towards risk appetite for financial investment decision.

H_I - Individual Income (Yearly) and Risk Appetite for Financial Investment Decision

In order to know the association between Individual income (yearly) and risk appetite for financial investment decision, the Pearson's chi-square test at 5% significant level has been carried out. Furthermore, to investigate the difference among individual income (yearly) towards risk appetite, the Kruskal Wallis test has been performed. For this purpose, the following null (H_0) hypothesis and alternative (H_A) hypothesis have been proposed.

H_0 : There is no significant association between individual income and risk appetite for financial investment decision.

H_A : There is a significant association between individual income and risk appetite for financial investment decision.

Based on analysis performed with the help of SPSS, it is observed that calculated value of chi-square for risk appetite regarding financial investment decision is 22.323. The p values of these investment avenues at 5% significant level 0.014. As the calculated value of p is less than the critical value, so we could null hypothesis and conclude that there is a significant association between individual income and risk appetite for financial investment decision.

H_0 : There is no significant difference among individual income towards risk appetite for financial investment decision

H_A : There is a significant difference among individual income towards risk appetite for financial investment decision.

Based on analysis performed with the help of SPSS, the p value of population median at 5% significant level of risk appetite for financial investment decision is 0.026. As p

value is less than the critical value, so we reject null hypothesis, which means there is a significant difference among individual income towards risk appetite for financial investment decision.

5. CONCLUSION

The purpose of this study was to investigate the effect of demographic variables on attitude towards risk with respect to financial investment decision. It has been found from the literature review that demographic variables have a significant impact on the investors' attitude towards risk. From the results of chi-square analysis, Mann-Witney test and Kruskal Wallis test, it has been concluded that demographic variables do have significant impact on risk appetite for financial investment decision. It has been observed that there is a significant association between gender, age, qualification, occupation, family income (yearly) and individual income (yearly) and attitude towards risk for financial investment decision. Whereas, marital status, ethnic groups and family type do not have impact on risk appetite for financial investment decision which is controversial to the previous research (Sung and Hanna, 1997). From the literature survey, it was found that ethnic group, race and religion have no significant impact on risk tolerance level of individual (Strydom and Metherell, 2012). From the chi-square analysis and Kruskal Wallis test, it was observed that there is no significant association between different ethnic groups and risk appetite for financial investment. Additionally, it was also found that there is no significant difference between ethnic groups among attitude towards risk for financial investment decision. It was consistently observed from previous research that marital status do have impact on risk tolerance level of individual that married respondents are more risk tolerant than single respondents (Grable, 2000; Grable and Lytton, 2003; Selcuk et al., 2010). However there is a controversial finding related to marital status. The findings suggested that there is no significant effect of marital status on risk appetite of investors for financial investment decision. Majority of the studies reported that qualification plays an important role in acceptance of risk associated with particular financial investments (Anbar and Ekbar, 2010; Grable, 2000; Corter and Chen, 2005). Contrarily, other researcher did not find any significant influence of education on financial risk tolerant level (Hallahan et al., 2003; Selcuk et al., 2010; Strydom and Metherell, 2012). The finding revealed from the chi-square test and Kruskal Wallis test that there is a significant influence of qualification on attitude towards risk while making financial investment decision.

6. MANAGERIAL IMPLICATION

The findings of the study would be useful to investment managers, financial advisors and brokers/ agents. It has been observed that many researchers have studied the

relationship between demographic variables, geographic variables and socio-economic variables, which have influence on attitude of investors towards financial investment. This study provides valuable insight into how demographic variables affect an investors' subjective financial risk appetite and as such contributes to a better understanding of how individuals make financial decisions in Surat city, India. The study would help in assisting financial advisors to provide financial advice that suits the individual needs of investors. Investment managers and financial advisors can use some demographic characteristics for differentiating and classifying investors into different risk-tolerance categories. This study would also contribute to the general knowledge in the field of behavioral finance by providing some results about relations between demographics and financial risk appetite.

7. GLOSSARY

Lakh – INR 100,000
Crore – INR 100,00,000
Ethnic Group A – Hindu
Ethnic Group B – Islam
Ethnic Group C – Jain
Ethnic Group D – Others
SD – Standard Deviation

Aquaculture Industry (Shrimp Farming): A Highly Productive Small Scale Industry for the Coastal Regions of Gujarat

Vatsal B. Patel, Vinod B. Patel

Department of Business and Industrial Management,
Veer Narmad South Gujarat University, Surat, Gujarat, India

Abstract: Aquaculture industry has evolved into a major contributor to Indian economy in a short period of time in terms of the foreign exchange contributor, employment generation in rural areas and its impact on the socio economic variables in the society. Shrimp farming is turning out to be a major activity for aquaculture farmers in rural coastal areas of India, due to its high earning potential. Suitable land i.e. brackish water environment is an essential requirement for shrimp farming. Currently India ranks 2nd only to china in terms of aquaculture production, however, India's total production is only 1/20th of that of china. Underutilization of brackish water land for shrimp farming has been an area of concern. This paper is an attempt to study the potential of the coastal regions of Gujarat in terms of shrimp farming in Gujarat.

Keywords: Aquaculture, Shrimp farming, Small Scale Industry, Rural entrepreneur, Gujarat.

1. INTRODUCTION

Aquaculture is generally considered a part of fisheries science, however there is distinction between the two terms 'fisheries and aquaculture', because of some basic differences in development and management. Aquaculture is defined by The Japanese Resource Council Science and Technology Agency as:

"Aquaculture is an industrial process of raising aquatic organisms up to final commercial production within properly partitioned aquatic areas, controlling the environmental factors and administering the life history of the organism positively and it has to be considered as an independent industry from the fisheries hitherto."

Aquaculture is referred to as an organized cultivation of a crop in the aquatic medium. It includes production of an animal or a plant. Two factors distinguish aquaculture from capture fisheries:

- Intervention in order to enhance stock
- Ownership of the stock.

The traditional ways of fishing from the seas and oceans has reached to a point where the resources are reducing at very fast pace due to excessive and irresponsible fishing during the recent time. During such circumstances aquaculture production must increase in order to maintain or increase the global seafood supply per capita. Aquaculture is of great importance worldwide, serving as an alternative source to traditional food production systems to help accommodate expansion of the human population.

During the last decade there has been a global upsurge for aquaculture. Modern aquaculture has developed into a dynamic, often capital intensive business frequently controlled by vertically integrated corporate giants of the food and retail industry. There have been major increases in aquaculture productivity along the entire production and supply chain.

Aquaculture in India has a long history, there are references to fish culture in Kautilya's Arthashastra (321 – 300 B.C.) and King Someswara's Manasoltara (1127 A.D.). The traditional practice of fish culture in small ponds in eastern India is known to have existed for over hundreds of years.

Aquaculture in India, in general, is practiced with the utilization of low to moderate levels of inputs, especially organic based fertilizers and feed. India utilizes only about 40% of the available 2.36 million hectares of ponds and tanks for freshwater aquaculture and 13% of a total potential brackishwater resource of 1.2 million hectares, in other words there is room for both horizontal and vertical expansion of these sectors. With over 8000 km of coastline there is immense potential for the development of mariculture which has taken roots only in recent years with culture of mussels and oysters. The production of carp in freshwater and shrimps in brackishwater form the major areas of activity.

India is the second largest producer of fish in the world contributing to 5.68% of global fish production. India is also a major producer of fish through aquaculture and ranks second in the world after China. Fisheries sector occupies a very important place in the socio economic development of

the country. It has been recognized as a powerful income and employment generator as it stimulates growth of a number of subsidiary industries, and is a source of cheap and nutritious food besides being a foreign exchange earner. Most importantly, it is the source of livelihood for a large section of economically backward population of the country.

The fisheries sector is a source of livelihood for over 14.49 million people engaged fully, partially or in subsidiary activities pertaining to the sector. Besides, an equal number are engaged in ancillary activities in fisheries and aquaculture. Development of fisheries can ensure food security as well as tackle unemployment in these regions that are predominately inhabited by rural populace

2. LITERATURE REVIEW

B. Meenakumari from Indian council of agricultural research, New Delhi in her paper "Prospects of fisheries and aquaculture in India" studied the future prospects of freshwater and coastal aquaculture in India.

In the study of "Aquaculture: Challenges and Promise" by Peter J. Allen (2011) focuses on the food and other requirements for the culture aquaculture systems and also as how it affects the overall growth and productivity of the culture fisheries. the paper entitled 'AQUACULTURE AND ITS ROLE IN INTEGRATED COASTAL ZONE MANAGEMENT' by S.M. STEAD, G.BURNELL and P. GOULLETQUER focuses on the two main objectives: to aid the development of stronger interdisciplinary communication between the natural and social sciences and to improve the utility of available scientific information and knowledge; and to promote new perspectives on the sustainable use of coastal areas and natural resources. The paper also summarizes the debates following each of the three workshop thematic sessions: aquaculture and ICZM; socio economic and political dimensions; developing sustainable production systems; and identifies the key recommendations that may be applied to the formulation of policy on integrated aquaculture management in coastal and marine environments.

IN HIS STUDY 'AQUACULTURE DEVELOPMENT IN INDIA: A MODEL' ROYDEN NAKAMURA made an effort to identify the nationwide program implemented by India to promote aquaculture in its rural communities. The uniqueness of this programme lies in its ability to address socioeconomic and cultural factors of the society which were previously ignored by the aquacultural scientists.

3. AQUACULTURE GUJARAT: POTENTIAL AND STATUS

Gujarat is surrounded by sea from two sides and was also a part of the sea before cenezoic era. So it is obvious that the state contains inherent salinity in land and water. Tidal

amplitude of Gujarat coast is higher than other parts of West coast. This natural phenomenon has created vast stretches of marshy and saline lands all along the coast.

The coastal zone of Gujarat is widely affected by soil and water salinity. However, the nature and extent of salinity vary over the space and are directly related to the hydrology, coastal geomorphology and human interventions in the coastal region.

In addition to very low amount of precipitation, the coastal region is suffering from salinity problem due to three major reasons; namely inheritance, natural processes and manmade activities. In the areas of coastal Saurashtra and Kachchh region, the salinity has increased due to sub surface intrusion and surface ingress. Intrusion is through the extension of seawater into land aquifers, while the ingress is mainly through tidal run over on low level plains. Marine intrusion has taken place because of highly deep porous geological formation along with over withdrawal of ground water. Over withdrawal of ground water has made water table lower. This lowering of water table has resulted in saline water intrusion due to the process of reverse hydraulic gradient and capillary action.

As far as South Gujarat is concerned, the tidal water which travels upstream along river channels has not only contaminated surface water but also affected the quality of ground water due to percolation. The use of saline water for irrigation purpose makes the land saline and degraded. Soil salinity/inter alia is one of the major problems, which are being faced by the state. It is also the main reason for the severe land degradation in the coastal region. The climate of the state observes wide fluctuations during the year. The temperature varies between 2° C to 9° C in winter and goes up to 41° C to 46° C. in summer. The only source of rain for the state is the southwest monsoons.

TABLE 1: Fisheries resources of Gujarat state

Marine	
Length of coast line (Km)	1, 600
Continental Shelf ('000 sq km)	184
Number of Fish Landing Centers	121
No of Fishing villages	247
No of fishermen families	62, 231
Fisher folk population	3, 36, 181
Inland	
Total inland water bodies (lakh Ha)	4.26
Rivers & canals (Km)	3, 865
Reservoirs (Lakh ha)	2.43
Tanks & ponds (lakh Ha)	0.71
Rood plain lakes/derelict waters (lakh Ha)	0.12
Brackish water (lakh Ha)	1.00

4. ACTS AND POLICIES FOR THE REGULATION OF FISHERIES SECTOR IN GUJARAT

- Gujarat fisheries act – 2003
- Village pond fisheries policy – 2003
- Reservoir leasing policy – 2004
- Marine fisheries policy – 2004 (GOI)
- Coastal aquaculture authority act 2005 (GOI)
- Brackishwater land lease policy – 2007

5. BRACKISH WATER LAND LEASE POLICY (REVENUE DEPT)

- Lease period for 20 years in the first instance and extendable for another 20 years.
- Lease Rent @ Rs. 250/= per ha for the first three years, which will be doubled from Forth year onwards for individual beneficiaries up to 5 Ha
- Lease rent @ Rs 1000 /- per Ha for more than 5 ha up to three years which will be doubled from fourth year onwards.
- Individual beneficiary entitled for 5 ha. Cooperatives – 50 ha and Industrial houses- 100 ha.
- Dist. Collectors empowered to sanction up to 5 Ha to individual prawn farmer, for Coop. societies limit is up to 50 Ha.
- State Govt. can sanction more than 50 Ha.
- Lessee cannot be sub leased or land cannot be transferred.
- Lessee can mortgage the land to nationalized banks and other Govt. approved financial institutions to avail loans for aquaculture activities.

6. ONGOING FISHERIES DEVELOPMENTAL PROGRAMS

- Establishment of fresh water prawn seed hatchery.
- Fish culture through FFDA's
- Fish seed Production and rearing by employing local youths
- Reservoir Fisheries Development.
- Leasing out the fishing rights of reservoirs.
- Special Programmes for SC / ST's.
- Providing landing and berthing facilities.
- Providing infrastructure facilities.
- Repatriation of fishermen from Pakistan
- Fish marketing subsidy.
- Distribution of kerosene to fishing vessels on reduced rates.
- Supply of Insulated Boxes

- Promotion of brackish water aquaculture.
- Group insurance scheme for all active fishermen
- Housing schemes for fishermen.
- Training to the personnel and fishermen
- Extension activities Good management practices
- Strengthening of Fisheries Co operatives.
- Fisheries Resource Assessment.

7. DATA ANALYSIS & FINDINGS

In India, two types of aquaculture are practiced. These are freshwater aquaculture and brackish water aquaculture.

Brackishwater aquaculture involves breeding of fish that habitat the sea like sea bass, grey mullet, tiger shrimp and mud crabs. It is practiced in States like Gujarat, West Bengal, Andhra Pradesh, Kerala and Goa. Brackish water aquaculture in India is synonymous with penaeid shrimp aquaculture. Because of its rapid growth rate and better market price, black tiger shrimp (*Penaeus monodon*) began as the most important species for penaeid aquaculture, however in recent years with the introduction of SPF L Vannamei, species of shrimp, most of the share of total shrimp production in India comes from Vannamei shrimps.

Gujarat brackishwater aquaculture sector comprises of a large number of the farms having less than 2 ha of land holding. As a result small brackishwater aqua farms are scale inefficient as the bargaining power for cost effective purchase of inputs as well as selling price is curtailed due to relative low volumes leading to low profitability.

TABLE 2: Suitable Brackishwater Aquaculture Land Available and Allotted

Sr. No.	NAME OF THE DISTRICT	LAND AVAILABLE (HA)	LAND ALLOTTED (HA)
1	Valsad	5138.73	590.31
2	NAVSARI	12037.18	1522.44
3	SURAT	19200.00	1168.50
4	BHARUCH	33208.00	1436.00

9	RAJKOT	3200.00	0
10	KUTCHH	7834.00	0
	TOTAL	89340.91	4996.39

(Source: commissioner of fisheries, gandhinagar, Gujarat)

Fig. 1. Percentage of suitable land allotted in Gujarat state

Fig. 2. Percentage of land Allotted – Gujarat State – District wise

A total of 10 districts in Gujarat have an access to brackish water land. Bharuch, Surat and Navsari are among the top three districts in terms of available brackish water lands. These land areas are underutilized in terms of aquaculture industry as the overall allotted land for the purpose of shrimp farming in Gujarat accounts to only 5%. With regards to Surat, the total percentage of land allocated to shrimp farming is about 6% only.

Fig. 3. Year wise Pattern of Area Under Culture in Gujarat State (Ha)

Fig. 4. Year wise Pattern of Estimated production in Gujarat State (Mt)

On a national level, Gujarat is one of the dominant states in terms of shrimp culture production. There has been an upsurge in the past few years where in the area under

cultivation as well as the overall production of shrimps in gujarat state has accelerated. Among other factors that led to this expansion, availability of SPF Vannamei shrimps seeds was a major reason as it reduced the overall risk for the shrimp farmers engaged in the farming operations

For cultivation of vannamei shrimps, as compared to tiger shrimps no extra facilities or infrastructure is required. As a result a farmer who cultured tiger shrimp earlier can easily switch to vannamei farming without and further capital investments.

TABLE 4: Productivity of Tiger & vannamei Shrimps – state wise – for year 2015 – 16

	State	TIGER SHRIMP			VANNAMEI SHRIMP		
		Area (Ha)	Prod. (MT)	Productivity (MT/ha/Year)	Area (Ha)	Prod. (MT)	Productivity (MT/ha/Year)
1	West Bengal	50, 593	61, 998	1.23	1, 387	6776	4.89
2	Odisha	4, 552	9, 191	2.02	4, 439	19, 241	4.33

(Source: The marine products export development authority – MPEDA, INDIA)

Fig. 5. Productivity of tiger and vannamei shrimps – state wise

During the initial years when the aquaculture farming practices began in India, Tiger shrimp was a major cultivable species due to its size, weight and an overall higher selling value. However cultivation of tiger shrimps is considered to be a high risk activity due to its low resistance against diseases and high maintenance during the culture period.

Vannamei shrimps on other hand eliminates this disadvantage of tiger shrimps as vannamei can be treated for SPF seeds, i.e. Specific pathogen free seeds, which makes it more stable and has a higher resistance against the diseases. This eliminates the danger of crop loss to a farmer

and there by diluting the overall risk of shrimp farming operations. As a result during the recent previous years more and more farmers have shifted from tiger shrimps to vannamei shrimps as a primary species for cultivation.

Every state of India where shrimp farming is carried out, Vannamei exhibited a higher productivity as compared to tiger shrimps. As the per hectare output improves the overall production of shrimps also increases. In the year 2015-16, where the tiger shrimps farms had a productivity of 1.18, vannamei shrimps were cultivated at a rate of 6.87 mt/ha/year. Productivity of tiger shrimps and vannamei shrimps in Gujarat state were recorded at highest level with

3.12 mt/ha/year for tiger shrimps and 7.93 mt/ha/year for vannamei shrimps.

TABLE 5: Average Productivity of shrimp farming in Gujarat & India

	AVG. PRODUCTIVITY - GUJARAT	AVG. PRODUCTIVITY – INDIA
2001-02	1.259	0.654
2002-03	1.193	0.760

2014-15	6.813	3.319
2015-16	7.799	3.538

Fig. 6. comparison of productivity of shrimp farming : Gujarat - India

Gujarat has always been an out-performer in terms of shrimp productivity in India. Productivity of shrimp in Gujarat has been recorded at nearly double to that of India's average productivity. Suitable climate and better management practice among the small scale shrimp farmers in the state contributes to this improved performance.

In terms of absolute production quantity, Gujarat's total production is low as compared to states like Andhra

Pradesh and Tamil Nadu. Area under culture in Gujarat is very low as compared to these states which is a major cause for low absolute production of shrimps in the state.

TABLE 6: 3 and 5 years Moving average of estimated production of Shrimps in Gujarat.

	GUJARAT - EP	3 year MA	5 year MA
2001-02	680	#N/A	#N/A

2014-15	30156.82	16745.94	12538.76
2015-16	35499	25447.94	18360.16

Fig. 7. 3 year Moving average of estimated production of shrimps in Gujarat.

Fig. 8. 5 year Moving average of estimated production of shrimps in Gujarat.

A three year and a five year moving average charts of the estimated production of shrimps in Gujarat shows a constant and a smooth upward trend thereby indicating a further growth in the scale and production of shrimps in Gujarat. As the area under culture continues to rise, aquaculture sector in Gujarat holds high potential to emerge as a leading shrimp producer in the country. Gujarat produced more than 35,000 MT of shrimps in 2015-16, however it is only about 7% of the total production in India.

World marine fish stocks have experienced a continuous depletion over the past decade, which has led to a higher demand for cultured species of fishes to satisfy the high demand for sea food in the world. There has been a high demand for Indian shrimps in countries like USA and other European nations, which offers a huge growth potential for shrimp aquaculture in Gujarat.

8. CONCLUSION

A large area of Gujarat coastal regions possesses brackish water environment, suitable for the cultivation of shrimps. Nearly ninety thousand ha. Of brackishwater lands are available in the state of Gujarat which is among the highest as compared to other states in India. Gujarat utilizes only about 5% of the total land for shrimp farming. It indicates a huge upside potential for future development and an opportunity to convert such idle lands into shrimp farms, which would improve the overall production of shrimps in the state.

Brackish water areas due to high salinity content are unsuitable for agriculture activities, thus setting up of shrimp farms in such areas would not compete with the traditional agriculture activities in such areas.

Gujarat demonstrates highest productivity in terms of both the Tiger shrimps and L. Vannamei shrimps, so increasing area under culture in Gujarat for shrimp farming would ensure a higher production as compared to other states in India.

When the traditional methods of fishing have reached have exhausted, Shrimp farming has evolved as a major employment source of the people of coastal regions thereby improving the overall standard of living in such regions.

Brackish water shrimp farming in Gujarat acts as a small group of industrial mode of farming, where the farming area is more than 5 ha, and supported by large number of small stakeholder owning farms lesser than 2 ha who comprise around 90% of brackishwater farming community. With an increase in the shrimp farming practices, it gives rise to the development of other ancillary industries, like, feed mills, hatcheries and processing units, which further add to the overall dynamics of the aquaculture industry.

MCADA: Building an *Intranet* of Things & People for an Enterprise-Wide Operations Control

Narendra Patwardhan

Head – Operations, Godrej Aerospace, Godrej & Boyce Mfg Co. Ltd., Mumbai, India

Abstract: In the important field of ‘Operations Control’ the emphasis of prevalent systems is either on control through expensive automation ‘of’ the operations, or on control through human-dependent sign-off’s ‘at’ their end-points. As a result, these systems offer excellent technical control and excellent procedural control. However the ‘managerial control’ aspect that calls for a ‘necessary & sufficient’ depth & breadth of coverage is not addressed well by them. Further they involve costs, complexities, &/ or pose issues related to organizational behaviour, and information overload. MCADA (Managerial Control And Data Acquisition) system (patent pending) is an attempt to define a middle path to meet that unfulfilled objective by tracking only the ‘vital few’ things & people critical-to-business at the ‘vital few’ junctures (control points) ‘across’ the operations using very simple (cost-effective) technology with an in-built enforcement of procedures. MCADA draws from the developments in ICT field of technology like the automation systems do, and also gives an enterprise-wide coverage like the Business Process Mgt Systems. However it purposely avoids deep-diving and also avoids the de-focusing due to very large coverage span. This can give to the Management an optimal & practical control over operations; in any industry – Manufacturing or other.

Keywords: Operations Control, managerial control, data acquisition

1. INTRODUCTION

In the industry, if a right game is set up by Engineering, Finance & Marketing, ‘Operations’ can make or spoil it. Having already invested in the former three, no business really has the option to allow the fourth one to spoil the game. Exactly in the same way, looking into what it takes to make ‘Operations’ successful, if the ‘Planning’ is done in the right manner, it’s the ‘Control’ that decides the end result. In essence, ‘Operations Control’ is the name of the game!

Not surprisingly therefore, it has been a focus of many great technological developments using the power of ICT, like Manufacturing Execution Systems (MES), Supervisory Control And Data Acquisition (SCADA) systems, Distributed Control Systems (DCS), etc.

The ISA S95 Standard has collated the whole gamut into a well-formed model for implementation of the above developments in a structured manner.

The point to note is that they are all developed keeping ‘Manufacturing’ as their domain. Thus they are oriented towards the factory floor. Also the method is almost exclusively ‘automation’, requiring expertise and sophistication, and therefore substantial ‘hard’ investments.

Above systems have their own place, but the Business Managers need info & control on only a few critical parameters, and they need that not only in manufacturing but across all the operations.

On another front, the developments in the Business Process Management (BPM), or Product Lifecycle Management (PLM) space offer control by providing actionable info based on ‘user’ inputs.

These solutions are of universal nature (that is they go beyond ‘Manufacturing’). Here the method is to ‘understand & assimilate the concept and learn the software’ which requires education & training (& consultancy & continuous IT support) and a disciplined culture, calling for ‘soft’ investments in addition to hard money. The approach is to automate the organizational ‘procedures’ (typically defined by the Management Systems like ISO-9001 / AS-9100 / etc.) and the ‘Control’ part is ‘considered’ as taken care of by providing a plethora of alerts in the Users’ (including Business Managers’) mailboxes. The reliability of updates depends on the ‘quality’ of user inputs. Unfortunately the much-too-familiar ‘ignore-the-alerts’ mindset or ‘oh-I-forgot-to-update’ or ‘well-I-update-everything-on-weekend’ expressions make Business Managers wary of relying on these otherwise fantastic systems (for their core purposes) for intra-day or day-to-day overall control on operations.

Looking at the above discussion, with added levels in the ISA S-95 framework as below (Fig 1), there seems to be a grey area between the ‘procedure’-focused management systems and the ‘automation’-focused technological systems, which needs to be addressed to give the Business Managers a ‘necessary & sufficient’ control over the operations across the enterprise, at reasonable cost.

Fig. 1. Enterprise Control System (Purdue CIM Reference Model)

Managerial Control And Data Acquisition (MCADA) system is an attempt towards that, using best of both worlds i.e. the procedural neatness of the management systems (minus the human discipline related aspect) and the technological edge of the automation systems (minus the complexity & information overload), to a required extent. As the name suggests, it basically applies the Engineering fundamentals of ‘control’ used in SCADA systems but

expands the horizon beyond ‘Manufacturing’ like the Business Process Mgt Systems, by building an Intranet of Things & People.

2. LITERATURE REVIEW

The extensive literature review was carried out for Operations Control Systems which are as follows

TABLE 1: List of main Operations Control Systems

Name	Description	Reference Standard / Platform
MES	Manufacturing Execution System	SAP-CAMS (2010)
SCADA	Supervisory Control And Data Acquisition	Allen Bradley PLC (2010)
ECS	Enterprise Control System	ISA S95 Standard (2010)
AQMS	Aerospace Quality Management System	EN 9100 (2009)
PLM	Product Lifecycle Management System	PTC Windchill (2010)

3. RESEARCH METHOD

SCADA (Supervisory Control And Data Acquisition) is a representative widely-used control system in the industry, which is taken as the reference to understand the fundamental elements of control systems required in the industry.

3.1 Fundamentals of 'Control'

Let's take a look at a very common example of (an analog) control (Fig 2).

Fig 2 A basic Control System

Point to note is that to control a process we need a sensor to send an error / deviation signal if any, a controller who notes the error/deviation signal (w.r.t. a set point) and issues a control signal in response, and an actuator to make course correction happen.

Let's look at a more technical process control example (Fig 3)

Fig. 3. An advanced Control System

Again, the essential components (sensor, controller and actuator) remain the same with the addition of a logical electronic circuit to automate the things not requiring human intervention, (though providing for a manual override).

3.2 SCADA: Supervisory Control and Data Acquisition system

Let's now look at the real sophisticated example which is nothing but the SCADA (Fig 4).

Fig. 4. SCADA Architecture

This is how Engineering control grows in sophistication (albeit with some real cost implications).

4. MCADA: MANAGERIAL CONTROL AND DATA ACQUISITION SYSTEM

MCADA, the suggested Managerial Control System, is about picking up threads from the above progression, and applying it to 'operations control'. It's kept lean (and low-cost) by monitoring minimal parameters to gain an optimal control on all operations in a unified manner.

MCADA works on some fundamental aspects of operations as follows.

In operations, there happen to be two 'things' : 1) there is 'work', and 2) there are resources. The work moves from one resource to other (or vice versa), travelling (actually or virtually) from one workplace to another in that process.

The key to control operations therefore is to know where are these two 'things', and to make course corrections if/as required.

MCADA proposes a control mechanism to achieve that objective using some very simple means. A typical schematic arrangement looks as below (Fig 5).

Fig. 5. Schematic diagram of the proposed MCADA system

The ‘controllers’ define the ‘control points’ under their respective area (manufacturing, purchase, HR, Logistics, etc.) across the Value Chain. A simple technology like BarCoding is then used to collect information about presence of ‘things’ at those ‘places’. So, that way it is akin to building an *Intranet* of Things. The differentiating part however is that in MCADA, unlike IoT, we use organizational behaviour as the driving force rather than the technology, as explained in the working as below.

4.1 The principle of working:

MCADA requires all critical ‘things’ (including ‘people’) to be assigned ‘info-tickets’ with BarCodes, and all the ‘Control Points’ to be assigned ‘info-seat’ BarCodes. The system then tracks the movement of the ‘info-tickets’ across various ‘info-seats’. For example, a typical set can be as below:

Thing	Owner	Info-ticket	Info-seat
Materials (WIP)	Custodian	Work Order BarCode	Workstations, Delivery points
Employee	Self	Employee BarCode	Work-stations

4.2 The method of working:

Step-1

The ‘controllers’ issue info-tickets to people. A pre-decided set of info-tickets is scanned in a pre-decided sequence at the start of each operation at a ‘control point’. In the event of incomplete or incorrect data from actual scans, some optional hard controls are deployed, like appropriate relays to actuate / not actuate the respective machines so that the operation cannot be performed.

Step-2

At the end of each operation, again a pre-decided set of info-tickets is scanned to declare the completion of operation. Again, optionally the power supply to the respective machines can then be stopped, so that the next operations can start only after the required set of scans take place.

Step-3

The ‘controllers’ assign next operation to the people thus freed from the current operation. This can be done in advance if a certain schedule can be drawn, or can be done dynamically.

Step-4

The alerts on the next operation time & assignment are sent to the respective people, and also to the easily viewable display & alarm screens across the establishment.

Step-5

This is the most critical step that mandates the current

owner of the ‘info-ticket’ to transfer it to the next assigned owner. Until the next owner has taken ownership and declared so by scanning, the ‘info-ticket’ is stuck with the current owner (even though s/he may have completed the operation).

In case of disputes related to a person not ready to take custody due to any other reason than being already fully occupied, the info-ticket is handed over (again through a Scan) to the predecessor’s Manager who has to resolve it till it is handed over to the expected successor.

Refusing to take custody due to sufficient work available on the plate would actually be good, to implement the ‘pull’ system (ref : Lean thinking), and to highlight capacity issues if any.

Till the time the operation is not declared as completed, the Cycle Time is being clocked. Once the operation is declared complete, till the custody has not changed, the Flow Time is clocked. This gives vital inputs to the Production System Analysts / Industrial Engineers / Lean Experts.

Step-6

Additionally, the non/conformance to expected ‘form’ of the product at pre-defined junctures may be captured through login-controlled BarCode scans by QC people.

4.3 The ‘operations control’ through MCADA is achieved with three on-line PTP reports:

Basically there are two simple rules of this system :

- 1) the system is kept ‘aware’ of every ‘thing’ as being under the custody of some ‘person’, and as being at some ‘workplace’ (machine location, PC, Canteen, Security Gate, Training Centre etc.), always;
- 2) every change in custody is forced to be declared to the system by scanning of 3 BarCodes, associated with - i) the thing, ii) the person taking custody, iii) the workplace (machine, PC) where the hand-off happened.

Once the above is ensured, there are three reports that keep the operations under control.

- 1) *Display & alarm report flashed on screens* at prominent locations keeping the work assignments loud & clear to every-one, supported by individual SMS alerts, forming a visibility-pressure & no-excuse culture
- 2) *Snapshotreportfor managers* about which info-ticket is at which info-seat at the moment, colour-coded for deviation from plan, putting positive pressure to monitor & resolve deviations, making their core job easier to perform

- 3) *Timelinereport for individuals (& their managers)* on their own travel, the travel of info-tickets in their custody, again colour-coded for the On-Time performance

In addition, to enforce the discipline, a report about all the info-tickets in possession of a person is displayed along with colour-coding at the time of entry / exit swipe of attendance system every day. Appropriate rules are put in place so that the colour-coding serves as OK (Green), Warning (Yellow) or Action (Red) signals. The 'Action' could be to disallow attendance at certain level of Red signals.

(Some other positive incentivising may be built, like small rewards for being in Green always.)

4.4 "Business First" approach

As can be seen from above working, MCADA takes a "Business First" approach. It's a Business System first, and IT System later.

Like typical IT Systems, it DOES NOT 'focus' upon - 'modernization', 'integration platform', 'extracting more from ERP system', 'automation', 'scalability', 'downloading production orders from ERP', 'uploading production status to ERP', 'plant floor data management', 'workflow management', 'integrating ERP with Plant Systems', 'standard certified components reducing project risk', 'HMI' and so on; while it DOES provide similar benefits w.r.t. - 'traceability', 'genealogy', 'up-to-date inventory records', 'greater visibility & control', 'reduced lead time', 'increased throughput & product quality', 'improved labor utilization', 'regulatory compliance', 'environmental efficiencies', 'energy utilizations',

'optimizing manufacturing processes', 'operations logbook', 'technical parameter limits management', 'equipment life', 'incident reduction', 'KPI monitoring', 'SPC', 'OEE', and so on.

4.5 The cost factor

The cost of printing the BarCodes is very low, however the cost of Scanners may become an obstacle, if we need them in large numbers. Hence the alternative is SmartPhone Apps that can scan the BarCodes and upload the transaction details to the Server.

5. RESULTS, DISCUSSIONS, CONCLUSIONS AND FUTURE SCOPE

The prevalent IT Systems in Operations Management or Control domain, are typically an expansion of business by Automation providers into this domain, and thus have the same underlying focus. MCADA, being designed by IE & Lean experts, takes a much broader & higher viewpoint, so does not get into EWI or other controls where human intelligence under alert supervision and a bit of mistake-proofing can produce desired results. (Remember 'Autonomation'?!). Hence implementing MCADA or sustaining its implementation does not require Automation or ICT specialists.

MCADA system is designed (refer Fig 6) to collect minimal field information, transfer it to a central computer server, processed by a human controller or by a controller software, allowing the controller to monitor or control the entire enterprise system from any location in real time. The feedback from the controller (if any) is reflected in alerts displayed and sent to the managers or operators.

Fig. 6. Proposed MCADA Architecture

5.1 MCADA: Key Business Benefits

- 1) It's a novel concept. It provides a unified and objective method for an enterprise-wide control over ALL business operations. It controls the Enterprise in the same perfect manner in which a SCADA system controls a machine. It's configurable in the same way, reachable from across the globe, and reliable.
- 2) The key value-adding aspect of MCADA is that it tracks the movement of things & people in Time & Space throughout the value chain. The other key aspect is it puts the Lean philosophy in practice across the organization by building in Lean practices like 'Pull', 'Kanban', and 'Andon' into the operating system.
- 3) MCADA takes the lateral view of the business operations. While it is good to take the sequential or horizontal view when converting the business plan into tasks or jobs (the 'what' & 'how' & 'when' part), when it comes to control, it works better to monitor the 'time-table' resource-wise (the 'who' is 'where' & 'when' part). The reason for this is that the execution can falter because of the resources, unless the plan is bad in which case we need to go back to the drawing board and change the plan. In the latter case too, it's the feedback from the resource performance that can take us to that conclusion.
- 4) MCADA improves resource efficiency through constant visibility (literally through IP Cams if required) and therefore pressure on the resource users (or on the resources themselves, in case of people) about the work pending with them and about the speed expected. MCADA also improves 'managerial effectiveness' as the managers know where to pay attention when.
- 5) MCADA on purpose avoids diving deep 'inside' the business operations, thus remaining lean and generic in its applicability, attaining unified system and quick

business benefits without the complexities of managing any high-end technologies.

5.2 Conclusion

Being a lean & a generic solution, MCADA is applicable in any industry wherever 'operations' exist i.e. wherever the work flows from one workstation to another and is being worked upon by resources (including human). MCADA is not about collecting process data e.g. clinical data is not the subject matter of MCADA, it's the operations data - i.e. which patient was administered which dose at what time by whom in which room - that is maintained & controlled through MCADA. Hence MCADA can provide for a much-needed simple & enforceable tool for the Business Managers giving them the 'necessary & sufficient' and 'reliable' real-time info so that they can be on top of 'Operations' without bothering about their types & technicalities.

Therefore MCADA fills the gap (pointed out in the preamble) above Level-4 of ISA-S95 model and below the *Level-6 we added (Fig 7)*. The good part is that it draws info directly from Level-0, 1 & 2 utilizing existing controls or otherwise introducing very simple controls of its own. At the same time, it's not in conflict with other existing systems, in fact it can draw benefits out of it. For example, typically in large enterprises the Work Orders may be generated from ERP and used by MCADA. However, what MCADA really needs that they carry a BarCode. So, like in Small & Medium Enterprises, the WO's may be print-outs from an amateur Excel-based system. Thus MCADA provides a sort of fly-over from Level-0 directly reaching beyond Level-4! Of course, you can always take the road through Level-3, 4 if already built and continue to reap the benefits thereof. Further MCADA is not only about Manufacturing Operations, it can work equally well beyond Manufacturing. Thus MCADA goes beyond ISA-S95 scope by covering ALL business & supporting operations (like even including management of security, etc.). The diagram below summarizes the unmet need MCADA fulfils.

Fig. 7. Positioning MCADA in the Business System

A Review of Poisson Distribution for Better Understanding towards Newer Applications

Senthil K. Anantharaman

Department of Operations Management and Quantitative Techniques,
Indian Institute of Management, Indore, Madhya Pradesh, India

Abstract: The three major discrete distributions that use integer as random variable are Binomial, Poisson and Hypergeometric distributions. In this study, we primarily discuss about Poisson distribution which was discovered by Simeon-Denis Poisson in 1838. The applications of Poisson distribution in science, real world and more specifically related to healthcare services are described in detail. This is followed by a review of properties of Poisson distribution inclusive of certain higher order moments. Different type of Poisson distributions and their properties along with their applications are described in brevity. A section on methods to generate Poisson-distributed variables as well as a few methods like maximum likelihood, confidence interval for estimation of its key parameters has been briefly elucidated. Finally, distributions that can approximate Poisson along with certain distributions that Poisson distributions can approximate have been discussed to give the reader a wholesome view about this distribution.

Keywords: Approximations, Distributions, Health Care Applications, Poisson.

1. INTRODUCTION

Poisson distributions, named after Simeon Poisson are statistical tools that help in predicting the probability of certain key events that can happen, provided we know often how the event occurs in the past. Hence it gives the

probability that events can happen in an interval of fixed time. All the real-life situations where Poisson distribution plays a pivotal role always have some identifiable characteristics. Poisson distributions can also be generated from certain statistical experiments known as Poisson experiments. The Poisson probability is given by

$$P(x, \mu) = \frac{e^{-\mu} \cdot \mu^x}{x!} \rightarrow \text{①}$$

where $P(x, \mu)$ is the Poisson probability that there are x successes in a Poisson experiment, μ is the mean of number of successes that occurs in a specified region and period, x is the actual number of successes is occurring in a specified region and period and e is the base of natural logarithms and is a constant equal to 2.718. Success means any outcome that is being in the question that occurs. The various events need to be independent for the Poisson distribution to be applied i.e. if occurrence of one event does not affect the other event. It can be proved that the mean of Poisson distribution as well as the variance is equal to

The Poisson probability that is represented by equation 1 is also known as probability mass function. A close relation occurs between the Poisson distribution as well as the Exponential distribution whose description is given below.

“The number of occurrences of an event within a unit of time has a Poisson distribution with parameter μ if the time that has elapsed between any two successive occurrences of the event has an exponential distribution with parameter μ and that is independent of previous event occurrences.” (Ref: Statlect: The digital textbook). This can be expressed by the following example.

Consider that a sequenced random variable that follows the Poisson distribution i.e. a set of arriving phone calls that the specific call centre receives. If any time that elapses between two consecutive phone calls is following an exponential distribution and the time of arrival is independent with reference to all previous calls, then calls that the call centre is receiving in one hour is following a Poisson distribution. The concept is illustrated by the plot shown in Figure 1 below, a graph is plotted between time and calls received. The function in the graph makes a jump

in the upward direction each time on the arrival of a phone call. The time that is being elapsed between two consecutive phone calls follows the exponential distribution that is equal to the prescribed length of each horizontal segment in the figure 1 shown below. The call count that was being on the receiving end in 60 minutes follows a Poisson distribution and is highlighted by the curly brace.

Fig. 1

In the following section, we look at some of major applications of Poisson distributions in science and real world with specific focus on its health care based applications. In section 3 we look at properties of Poisson distribution, including some techniques, like adding two Poisson distributions that would be helpful in production, specifically in dealing with problems involving multiple assembly lines. Section 4 deals with diverse types of Poisson distributions. Section 5 briefly discusses about certain methods like maximum likelihood method for estimating parameters of Poisson distribution. Section 6 briefly describes about the software and commands that are used in software to generate Poisson distributions. The concluding section deliberates on certain approximations towards other distributions like binomial that Poisson distributions can be used for as well as certain other distributions that are approximations for Poisson distributions. By study of this paper, the author's intention is that both the novice and advanced reader in statistics gets a comprehensive view of this amazing distribution's power to apply in more new and sophisticated industrial applications.

2. SOME REAL WORLD AND SCIENTIFIC APPLICATIONS OF POISSON DISTRIBUTION

The purpose of this section of the paper is to bring about a cognizance of various applications of Poisson distribution and the opportunities it provides in real world cases.

Patients who are arriving at an well-equipped and designed emergency room, cars that drive for petrol to a petrol station, decaying of rays of radioactive atoms, a queue of

bank customers arriving at a bank, and finally shoppers being served at a cash register. All these events follow a Poisson process. For few more Poisson related examples, we have the following (Jerzy Letkowszki)

- Prussian Army soldiers killed by horse kick, though accidentally in a year (von Bortkewitsch, 1898, p. 25).
- Monthly bankruptcies filed. (Jaggia, Kelly, 2012 p.158).
- Car-washing of cars arriving. (Anderson et al., 2012, p. 236).
- Network failures that have occurred in a year (Levine, 2010, p. 197).
- Hungry persons entering McDonald's restaurant.

The above time-based Poisson variables are extremely popular in contrast to space oriented Poisson variables which are described below. (Jerzy Letkowszki)

- Fleas accumulated on top of a dog (Levine et al., 2011, p.).
- White bond paper blemishes. (Doane, Seward, 2010, p. 232).
- Bacteria multiplication. (Anderson et al., 2012, p. 237).
- The number of defects in a 50-yard roll of fabric or the number of bacteria in a specified culture (Jaggia, Kelly, 2012, p.158).
- Hazardous based waste sites in a country (Black, 2012, p. 161).
- Eagles that nest in a specific region (Triola, 2007, p. 252-253).
- Customer complaints on a service on a monthly basis (Donnelly, Jr., 2012, p. 215).
- Visitors on WWW per minute (Sharpie, De Veaux, Velleman, 2010, p. 654).
- Consumer hot line calls arriving in a 2-minute time period (Pelosi, Sandifer, 2003, p. D1).

Poisson distributions are extensively used in health care industry and hospitals. The phenomenon of variability, though not similar to automobile or production industry exists in health care industry also and the process of reducing variation improves both throughput and quality in delivery of the healthcare services. Here variation occurs, when random arrival of patients for some emergency situations results in scarce resources in the hospitals. The arrival of patients follows a multiple or compound or truncated Poisson distribution that is discussed in subsequent sections of the paper. Thus, an availability of mean arrival rates and its natural variability are extensively

used for planning of resources. Some complex problems involving patients who were not scheduled in the workload, randomly arriving patients, not enough number of ICU beds, OR Rooms, health staff etc. lead to lowering of efficiencies, high error rates leading even to many fatalities. Fortunately, a systematic study inclusive of queuing analysis, arrival patterns of patients can be safely said in following Poisson distributions and Poisson based regressions that have been of immense help in reducing these critical problems.

In some of the other major applications in health care, a few hospitals that have studied the admissions through its Accident and Emergency department to the ICW and MSW, have shown that the queueing model that has been selected, assumes that the daily admissions rate follow a Poisson distribution and this behaviour was confirmed here by goodness of fit test as illustrated in the following Figure 2. The arrival rate into Intensive Care Unit follows a Poisson distribution was proved by Green L.V(2002) and Milne and Whitty (1995). The occupancy rate (ρ) was found to be in correlation with the actual demand (λ) and hence LOS (μ) which can be defined as follows, $\rho = \text{Mean beds occupied} / \text{number of beds available} = (1 - P_c) \lambda \mu c$. The term $(1 - P_c)$ can be called as the absolute demand, as the admissions that have been refused can be subtracted from the actual demand. Also, $\lambda \mu$ is the final product which

is expected number of patients in the system, that is also represented by workload of the current system.

Fig. 2. Distribution depicting arrival rates in the system

Another major area where the Poisson distribution has been extensively applied and where it makes easy is in estimation in the number of births on a daily basis that can be used in planning the staff of obstetrics clinics whether it is of small or enormous size will not be an issue. An exemplification of different sizes of obstetrics clinics be it small, medium or large is shown in Figure 3 with births number on X-axis and Y-axis depicting density indicating the Poisson distribution in Red and green representing normal distribution.

Fig. 3.

3. PROPERTIES OF POISSON DISTRIBUTION

3.1 Expected Value of Poisson Distribution (or Random Variable):

For any given discrete random variable that is following a Poisson distribution having parameter the expected value of this variable is $E[X] = \lambda$

3.2 Variance of Poisson Distribution (or Random Variable):

For a given discrete random distribution and a variable X that follows a Poisson distribution having parameter the variance of this variable is $\text{Var}[X] = \lambda$.

3.3 Mode of Poisson Random Variable:

If λ is not an integer, the mode of a Poisson distribution having parameter λ is $[\lambda]$

Otherwise, both λ and $\lambda - 1$ are modes.

3.4 Median of Poisson Random Variable:

The median P of a Poisson distribution with parameter λ satisfies

$$\lambda_{\ln 2} \leq P \leq \lambda$$

3.5 Sum of two Independent Poisson distributions (or Random Variables):

Let X_1 as well as X_2 be the two Poisson random distributions or variables having parameters λ_1 and λ_2 , respectively. If X_1 as well as X_2 are independent, then $X_1 + X_2$ is also a Poisson distribution or random variable with parameter $\lambda_1 + \lambda_2$

Its distribution can be described with the formula

$$P(X_1 + X_2 = k) = \frac{(\lambda_1 + \lambda_2)^k \cdot e^{-(\lambda_1 + \lambda_2)}}{k!}$$

The above proof can be shown as below.

Let $X = Y + Z$,

we have now $P(X = x) = P(Y + Z = x) =$

$$\sum_{y+z=x} P(Y=y, Z=z)$$

$$= \sum_{y,z=0}^{\infty} P(Y=y) P(Z=z)$$

$$= \sum_{y=0}^{\infty} \frac{e^{-\lambda_1} \lambda_1^y}{y!} \sum_{z=0}^{\infty} \frac{e^{-\lambda_2} \lambda_2^z}{z!}$$

$$\begin{aligned} \text{Now } \frac{\lambda_1^y}{y! z!} &= \frac{(\lambda_1)^y}{y!} \frac{(\lambda_2)^z}{z!} \\ \text{or } P(X=z) &= \frac{e^{-\lambda_1} \lambda_1^y}{y!} \frac{e^{-\lambda_2} \lambda_2^z}{z!} \\ \text{from binomial theorem} \\ \text{last sum is } (e^{-\lambda_1} \lambda_1 + e^{-\lambda_2} \lambda_2)^z \\ \text{or } P(X=z) &= \frac{e^{-(\lambda_1 + \lambda_2)} (\lambda_1 + \lambda_2)^z}{z!} \end{aligned}$$

Therefore, X has a distribution following Poisson with parameter $\lambda_1 + \lambda_2$.

4. SOME TYPES OF POISSON DISTRIBUTIONS WITH THEIR APPLICATIONS

One of the major types of Poisson distribution is the bivariate Poisson distribution which has been extensively used in modelling sports related data which has two outcome variables. Bivariate distributions are used primarily as it allows dependence between two random variables.

The other type of Poisson distribution is multivariate Poisson distribution that has been essentially been used in numerous applications, some of them are multi echelon based supply chain distribution systems, multi-item as well as multi-period pricing and costing models, as well as effective accident monitoring systems, etc. To set the pricing of non-durable products like for example (e.g. cosmetics, certain perishables like fashion, supplies in an office) on a definite as well as finite, multi-planning time period has been a nontrivial problem and it has been found that simulation based on multi variate Poisson models has been extremely useful for such type of models. Another major application of multi variate distributions is in bio-surveillance. A major aspect of bio-surveillance is an early and absolute time based detection of chronic disease based outbreaks. A major feature and quality of bio-surveillance data is that it exhibits multiplicity in numerous dimensions, inclusive of factors as multiple data sources (e.g. pharmacy and sales of medicine, hotline calls regarding availability of nurses, and emergency based department visits), multiple available locations (e.g. different hospitals within a certain and provided geographical area), multiple symptoms of various diseases, etc. Multi-variate monitoring, hence is

receiving a phenomenal attention and hence bio-surveillance data has also been placed on radar in literature.

5. METHODS FOR ESTIMATING PARAMETERS OF POISSON DISTRIBUTION

In many problems, we come across a situation where it is not that clear on what type of estimators are appropriate for a distribution, but still there are a few methods to derive the estimators and we will consider the methods that are useful for estimation of Poisson distribution. They are usually 1) the maximum likelihood method as well as 2) the method of moments. Though the method of moments may look simpler, it is the maximum likelihood method that provides better estimation.

The maximum likelihood estimator of say Poisson distribution having a parameter λ can be written as below

We Poisson distribution

$$f(x) = \frac{e^{-\lambda} \cdot \lambda^x}{x!} \quad (x=0, 1, 2, \dots)$$

and normally $\frac{d}{d\lambda} f(x, \lambda) = 0$

$$\text{Max}(l(\lambda)) = \frac{d(l(\lambda))}{d\lambda} = 0 \quad \text{or}$$

$$\lambda - \frac{\sum_{i=1}^n x_i}{n} = 0 \Rightarrow \lambda = \frac{\sum_{i=1}^n x_i}{n} = \text{mean}$$

Thus, we see that maximum likelihood estimator λ is just the sample mean of n observations in the provided sample.

The method of moments also estimates multiple moments of a distribution and here in this section we show how we have come up with first, second and third moments of Poisson distribution having a parameter

First Moment of Poisson Distribution

$$\begin{aligned} \mu_1'(\lambda) &= \sum_{x=0}^{\infty} x \cdot \frac{e^{-\lambda} \lambda^x}{x!} \\ &= e^{-\lambda} \lambda \left[1 + \frac{\lambda}{2!} + \frac{\lambda^2}{3!} + \dots \right] \\ &= e^{-\lambda} \lambda \cdot e^{\lambda} \\ &= \lambda \end{aligned}$$

Second Moment of Poisson distribution

$$\mu_2'(\lambda) = \sum_{x=0}^{\infty} x^2 \cdot \frac{e^{-\lambda} \lambda^x}{x!}$$

$$\begin{aligned} &= e^{-\lambda} \lambda^2 (1 + \lambda + \lambda^2 + \dots) + \lambda \\ &= e^{-\lambda} \cdot \lambda^2 \cdot e^{\lambda} + \lambda \\ &= \lambda^2 + \lambda \Rightarrow \mu_2'(\lambda) = \lambda^2 + \lambda \end{aligned}$$

Third moment of Poisson distribution is $\mu_3'(\lambda) = \sum_{x=0}^{\infty} x^3 P(x)$

$$\begin{aligned} &= \sum_{x=0}^{\infty} \{x(x-1)(x-2) + 3x(x-1) + x\} P(x) \\ &= \lambda^3 + 3\lambda^2 + \lambda \end{aligned}$$

$$\begin{aligned} \text{or } \mu_3 &= \mu_3'(\lambda) - 3\mu_2'(\lambda) \cdot \mu_1'(\lambda) + 2(\mu_1'(\lambda))^3 \\ &= \lambda^3 + 3\lambda^2 + \lambda - 3(\lambda^2 + \lambda)\lambda + 2\lambda^3 \\ &= \lambda \end{aligned}$$

Thus, we see first, second and third moments are the same for Poisson distribution and is equal to the parameter λ . The derivations in this section gives the reader for estimating the parameters of our Poisson distribution using moments technique and likelihood function. This will aid the reader to apply these estimation techniques specifically for the applications and problems involving samples that follow Poisson Distribution.

6. SOME APPROXIMATIONS

In the concluding section of this paper, the author provides a terse review of approximations under which Poisson distribution acts as an approximation to binomial distribution. When in binomial distribution becomes large i.e. as 'n' approaches to infinity ($n \rightarrow \infty$), 's' tends to zero ($s \rightarrow 0$), then $n \cdot s$ which is the mean, tends to a constant.

Then, the binomial probability mass function which is $\frac{n!}{x!(n-x)!} s^x (1-s)^{n-x} \rightarrow \frac{e^{-\lambda} \lambda^x}{x!}$ which is the Poisson distribution.

This is also known as Poisson Limit Theorem. Normal distributions are also extensively used for approximating

Poisson distributions when the parameter λ becomes large. These approximations give a more accurate picture while performing the hypothesis tests as they are also rational in the approach. Further it has already been found out that the approximations for Poisson distributions has been very effective in single period inventory model. This makes the use of approximations in real world applications more beneficial.

7. CONCLUDING COMMENTS

The paper's main objective is to get an understanding by exploring Poisson distributions, its applications, certain properties, distinct types of Poisson distributions, methods to explore the estimation of its parameter and finally the way it aids its users through its approximations. The conclusions that can be arrived at a broader sense is that it is certainly undeniable, that Poisson distribution has a greater width of applications in the future, be it the sports industry or the health care service industry where we had a glimpse of its usefulness. Use of Poisson distributions has also additionally benefitted the researchers in prediction of certain problems which can now be solved more accurately and deftly.

Traceability Management System Using RFID in Vehicles for Parking: A Review

A. Chandrashekhar, M. Noel Veron

Department of Mechanical Engineering, Faculty of Science and Technology,
IFHE University, Hyderabad, Andhra Pradesh, India

Abstract: Using long range RFID enables users to gain access the easy way: a transponder or tag behind the windshield or otherwise attached to the car, is remotely read by a long range reader. Without any delay the barrier opens and the vehicle can pass through. Long Range Automatic Vehicle Identification Systems offers the highest level of convenience you can offer to your employees, suppliers and customers. AVI systems are designed to be connected to access control systems. The same systems you use for building access control, can also be extended to support vehicle access control which will enable you to extend the development of security policies. Time schedules and conditional authorizations can easily be implemented for vehicles.

Keywords: RFID (Radio Frequency Identification), AVI (Automatic Vehicle Identification), Transponders,

1. INTRODUCTION

Radio-frequency identification (RFID) is an automatic identification method, relying on Storing and remotely retrieving data using devices called RFID tags or transponders. The technology requires the cooperation of an RFID reader and an RFID tag. An RFID tag is an object that can be attached to an object for the purpose of identification and tracking. This can be done by using radio waves. Some tags can be read from several meters away and beyond the line of sight of the reader. An RFID tag is an object that can be incorporated into a product, here it is vehicles for the purpose of identification and tracking using radio waves.

Vehicle tracking has increased in use over the past few years and, based on current trends, this rise should continue. Tracking offers benefits to both private and public sector individuals, allowing for real-time visibility of vehicles and the ability to receive advanced information regarding legal existence and security status.

2. RELATED WORK

The present day metropolitan areas have seen a burgeoning growth in human population as well as vehicles. With shrinking spaces, operating a managed, busy and expensive parking lot having multiple gates can pose significant challenges, especially to a private organization that also owns some of the vehicles in the lot. The parking area has to be secure, with barrier-enforced entrances and exits. It also has to have an automated, efficient monitoring system that allows for accurate vehicle tracking as well as easy in-and out access for drivers.

With this RFID vehicle tracking system, vehicle information can be automated gathered to enable vehicle management to be more efficient and safe. With RFID vehicle tracking system with high identification accuracy, parking areas or gated communities can manage their vehicles efficiently without human intervention as well as easy in-and-out access for drivers and with low deployment and operation cost. RFID's also offers a turnkey solution for parking operators that require the ability to monitor and record not only access and exit to parking facilities but also log and bill back parking charges by customer.

3. COMPONENTS OF RFID

A basic RFID system consists of three components:

- i. An Antenna or coil
- ii. A transceiver (with decoder)
- iii. A transponder (RF tag) electronically programmed with unique information

Fig. 1. Working of RFID System

3.1 ANTENNA

The antenna emits radio signals to activate the tag and read and write data to it. Antennas are the conduits between the tag and the transceiver, which controls the system's data acquisition and communication. Antennas are available in a variety of shapes and sizes; they can be built into a door frame to receive tag data from persons or things passing through the door, or mounted on an interstate tollbooth to monitor traffic passing by on a freeway. The electromagnetic field produced by an antenna can be constantly present when multiple tags are expected continually. If constant interrogation is not required, a sensor device can activate the field. Often the antenna is packaged with the transceiver and decoder to become a reader, which can be configured either as a handheld or a fixed mount device. The reader emits radio waves in ranges of anywhere from one inch to 100 feet or more, depending upon its power output and the radio frequency used. When an RFID tag passes through the electromagnetic zone, it detects the reader's activation signal. The reader decodes the data encoded in the tag's integrated circuit (silicon chip) and the data is passed to the host computer for processing.

3.2 TAGS (Transponders)

An RFID tag is comprised of a microchip containing identifying information and an antenna that transmits this data wirelessly to a reader. At its most basic, the chip will contain a serialized identifier, or license plate number, that uniquely identifies that item, similar to the way many bar codes are used today. A key difference, however is that RFID tags have a higher data capacity than their bar code counterparts. This increases the options for the type of information that can be encoded on the tag. The amount of data storage on a tag can vary, ranging from 16 bits on the low end to as much as several thousand bits on the high end. Of course, the greater the storage capacity, the higher the price per tag. Like all wireless communications, there are a variety of frequencies or spectra through which RFID tags can communicate with readers. Low-frequency tags are cheaper than ultra-high-frequency (UHF) tags, use less power and are better able to penetrate non-metallic substances.

3.2.1 TYPES OF RFID TAGS

3.2.1.1 ACTIVE TAG

The active tags battery-powered and always well active. It is consistently on the lookout for a reader's signal.

3.2.1.2 PASSIVE TAGS

The passive tag relies on energy transferred from a reader to power up and transfer its information.

3.2.1.3 SEMI-PASSIVE TAGS

Semi-passive tags also use their battery to send radio waves to a RFID reader, where as these tags rely on the reader to supply power for its broadcasting.

3.2.2 FREQUENCY OF OPERATION

3.2.2.1 LOW FREQUENCY

Works on the principle of Inductive coupling. LF band ranges from 125 KHz to 134 KHz. This frequency band provides a short range of 10cm and has slower read speed than the higher frequencies, but is not very sensitive to radio wave interference.

3.2.2.2. HIGH FREQUENCY

Works on the principle of Inductive coupling. HF band ranges from 13.56. Frequency read ranges from 10cm to 1m. These systems experience moderate sensitivity to interference.

3.2.2.3. ULTRA HIGH FREQUENCY

Works on the principle of Electro Magnetic coupling. UHF band ranges from 860 MHz to 960 MHz Frequency range is up to 10m to 15m and UHF RFID has a faster data transfer rate than LF or HF and is the most sensitive to interference.

3.3 RFID Reader

A device used to communicate with RFID Tag. The reader has one or more antennas, which emits radio waves and receive signals back, from the RFID Tag. Also called Interrogator because it interrogates the RFID Tag. Data retrieval - RFID Reader – Device - Emits radio waves - Received by the RFID Tag - Activates the microchip data get transmitted.

Fig. 2. Vehicle with RFID tag approaching RFID reader

4. SOLUTION

A simple parking lot layout is shown in figure-3. When a vehicle with an RFID tag enters the parking lot, the RFID reader reads the tag and notes the in time and opens the barricade. As soon as the vehicle enters parking lot and approaches the reader at the entrance monitor inside the parking lot shows which parking lane is free so that the driver can park the car. Every parking lane in the parking lot must have a RFID reader to sense if a vehicle is parked in that lane or not, or every pillar must have a reader which reads number of tags in its oriented direction. That means it reads number of vehicles parked in the oriented direction. This gives information of the empty parking lanes for the new coming vehicles to park which is displayed in the monitor. At the exit as if RFID is linked with the prepaid accounts, charges for the parking will automatically be

debited from their accounts based on time parked. Barricades at the exit open when a vehicle approaches the reader at the exit. For payment we need an online site where

user can pay later without waiting in the queue at the .Using this online site users can also be given access to pre-book their parking lane for convenience.

CAR PARKING LAYOUT BLOCK A

Fig. 3. Basic Parking lot layout

For this to happen we need many readers to read the tag on the vehicles, so there is a need for reduction of high priced RFID readers and make them economical for a firm to adopt this technology. Low frequency and high frequency tags can be used in parking lots, as very large frequency ranges are not suggested as they are not economical for day to day use.

5. CONCLUSION

RFID technology provides independent, non-stop tracking systems for security, parking, and access control. This technology provides businesses and communities with hands-free control to ensure only authorized vehicles have entry. RFID park lot management system is one of the few real-time locating systems that provide fast return of investment (ROI). System helped user reduce the time wasted in searching for parking place and also improve the parking lot utilization.

Study on Small Scale Manufacturing Industries in India- Some Aspects of Size, Growth and Structure

Ratnesh Gupta, Atul Kumar Srivastava, Ashish Kumar

Department of Mechanical Engineering, Pusa Institute of Technology, Delhi, India

Abstract: The aim of this research paper is to study and analyze the problems faced by the the small-scale sector in India by the non-factory non-household segment of the manufacturing sector while working in global market. It is found to be a significant source of manufacturing employment. Small businesses often face a variety of problems related to their size. A frequent cause of bankruptcy is undercapitalization. This is often a result of poor planning rather than economic conditions. It is a common rule of thumb that the entrepreneur should have access to a sum of money at least equal to the projected revenue for the first year of business in addition to his anticipated expenses. A rigorous literature review has been done to identify the problems faced by Indian Small Scale Industries. The most important factor for economic development of a country is its industrialization. In India, Development is designed in such a way to remove poverty, unemployment and backwardness of the rural people. According to their nature, the problems have been classified into different sections like market problems, technological problems, production problems etc. Authors have observed that increased production cost and tough competition were among the biggest problems faced by Small Scale Industries. Finding of the current research can help the Indian SSIs in identifying the problems and make strategies to remove these problems.

Keywords: Small Scale Industries, Entrepreneurship, Production Problems, Market Problems, Employment Prospects

1. INTRODUCTION

Cottage and small-scale industrial sector plays a dominant role in the economic development of both developed and developing countries. A major objective of planned economic development has been industrialization and employment generation. In developing countries cottage and small-scale industries are especially important in context of employment opportunities, equitable distribution of national income, balanced regional growth and development of rural and semi urban areas. They provide immediate large-scale employment, offer a method of ensuring a more equitable distribution of the national income and facilitate effective mobilization of resources of capital and skill which might otherwise remain unutilized.

India is based on several culture and civilization. With the passage of time, India has been tremendously changed the whole scenario. Industry has played a crucial and pivotal role in developing nation and India to be digital which is the backbone of the nation. In Indian economy small-scale and cottage industries occupy an important place, because of their employment potential and their contribution to total industrial output and exports. Government of India has taken a number of steps to promote them. However, with the recent measures, small-scale and cottage industries facing both internal competition as well as external competition.

Small scale industries, including traditional cottage and village industries and modern small enterprises have been given an important place in India's economic planning for

ideological and economic reasons. Our late Prime Minister Mrs. Indira Gandhi once remarked, "Small scale industries offer many opportunities; besides adding to production, they broaden the industrial base. They enable the process of modernization as well as entrepreneurship to spread to more regions and layers of society".³ Father of our Nation, Mahatma Gandhi ji had strongly advocated the development of Indian villages by making them financially viable through small and village industrial units. The small scale and cottage industries also play an important role in removing regional disparities. The industrial development in a backward area can only be achieved by the rapid development and promotion of small scale industries. Besides economic aspects, the social role of small scale and cottage industrial units are quite significant in achieving various social goals such as removal of poverty, attainment of self-reliance, reduction in disparities in income, wealth and standard of living and regional imbalances..

According to the provision of Micro, Small and Medium Enterprise Development (MSMED) Act, 2006 the micro, small and medium enterprises are classified into two classes (a) Manufacturing Enterprises- The enterprise engaged in the manufacture or production of goods pertaining to any industry specified in the First Schedule to the Industries (Development and Regulation) Act, 1951. The manufacturing enterprises are defined in terms of investment in plant and machinery and Service Sector-

1) The enterprises engaged in producing or rendering of services and are defined in terms of investment in plant and

machinery. The limit for investment in small manufacturing enterprises is more than Rs. 25 lakh but does not exceed Rs. 5 crore and that of service enterprises is more than Rs. 10 lakh but does not exceed Rs. 2 crore.

Traditional small scale industries includes Khadi and Handloom, Handicraft, Village industries, Bamboo based industries, Sericulture and coir etc. Modern small scale industries produce a wide spectrum of goods ranging from comparatively simple items to sophisticated products such as television sets, electronic control system, mixer grinder and various engineering products particularly as ancillaries to the large industries. The traditional small industries are highly labor intensive, while the modern small scale units use highly sophisticated machinery and equipments

Programmes for modernization and upgrading of technology in the small scale sector to improve their competitive strength will be implemented. A new bank known as Small Industries Development Bank of India (SIDBI) has been established to channelize need based higher flow of credit, both by way of term loan and working capital to the tiny and rural industries. To help the artisans working with Khadi and Village Industries Commission (KVIC) and KVI Board, special Marketing organization at the Centre and State level shall be created. People are choosing any small scale and cottage industry without technical knowledge, its viability and profitability etc. Sometimes they succeed in getting loans from financial agencies to start a small scale or cottage industry. Loans received without knowledge of its proper and optimum utilization often leads to poor recovery by the lending agencies which also create problems in smooth functioning of these financial institutions. The present study aims to provide a concrete and proper ideas and information about all the factors discussed above. This work may prove to be the pathfinder to the new generation who are roaming here and their and chasing after jobs. This research would be of immense help to the common people, the policy makers, government officials, researchers and also to other non governmental organizations who are engaging themselves in the upliftment of the poor in particular and the socio economic development of INDIA as a whole.

2. LITERATURE REVIEW

A thorough review and survey of related literature forms an important part of research. It deals with the critical examination of various published and unpublished works related to the present study. Knowledge of related research enables the researcher to define the frontiers of his fields; it helps in comparing the efficiency of various procedures and instruments used⁴. Further review of literature avoids unintentional replication of previous studies and also places the researcher in a better position to appreciate the significance of his own results.

In the early literature on economic growth and development, industrialization as a source of employment and capital accumulation has been recognized by various economists. Here Ashish et al highlights the review of works.

For the first time, J.M. Keynes (1936) has focused his attention on the forces that determine employment policy followed in industrialization. He propounded the theory that entrepreneurs will offer the amount of employment which maximizes their output and profit.

According to Keynes “employment can only increase pari passu with an increase in investment”. W.A. Lewis (1954)⁶ has strongly advocated the application of labor intensive techniques of production to have a steady and smooth economic growth. He opined that many important works can be done by human labor with very little capital. Efficient labor could be used to make even capital goods without using any scarce factors. In this sense, small scale and cottage industry should be developed and promoted especially in an economy where capital is scarce.

Leibenstein and Galenson (1955) took an opposite stand and tried to show that labor intensive techniques might generate immediate output but little surplus since the wage bill would be large. Economic development preceded investment but the use of labor intensive a technique leaves little surplus for investment.

Dhar and Lydall (1961)¹⁰ made their study on the data collected from Census of Indian Manufactures, 1956 and the study prepared by the Perspective Planning Division of the Planning Commission in respect of capital, labor and output relations in various industries. They concluded that the issue of choice between large and small industries for the purpose of an employment-oriented industrialization strategy is largely irrelevant.

Professor Gunnar Myrdal (1968) recommends the adoption of a strategy based on predominantly laborintensive techniques in less developed countries on the ground that “the large volume of unutilized labor possessed by these countries has a productive potential, capable of creating capital and increasing production”.

According to the Village and Small scale Industries Committee Report (1955), popularly known as Karve Committee Report, since a substantial number of employed and underemployed belongs to the village and small industries group, setting up of small scale and village industries will provide employment to them in occupations in which they have been traditionally trained and for which they possess equipments.

3. HYPOTHESES

To meet the objectives of the study, the following hypotheses are postulated in the study:-

1. The area suffers from excessive and acute unemployment and under employment problem.
2. Persons suffering from underemployment are interested in taking up complementary jobs to uplift their level of living.
3. There is a lack of innovations and entrepreneurship in the state.

4. METHODOLOGY AND DATA BASE

In order to achieve the objectives our present study requires both primary and secondary data. Accordingly, a field survey has been conducted to obtain primary data adopting a sampling design of “two stage purposive sampling” with the selection of industries at the first and industrial units at the second stage. Information is obtained from the eight districts namely Bulendshaer, Alwar, Rewari, Hapur, Pilukhwa, Muradnagar, Amroha, Bahadugarh about the existing cottage and small scale industries.

In order to accomplish the objectives, the present study is mainly based on both primary and secondary sources of information. The secondary data is mainly congregated from published and unpublished works on the related topics. Census reports, economic surveys, journals, news papers, government and non government organizations (NGOs) associated with the industrial sector especially the Directorate of Industries, Directorate of Economics and Statistics, Directorate of Agriculture and Minor Irrigation.

Consequently, the final questionnaires were distributed among the owners, entrepreneurs or managers. Besides, unstructured interview and informal discussions were also held with the owners and workers SSI units. Due to the fact that majority of the SSI units in the state do not maintain proper account of their business, it was not possible to gather time series data on the variables like investment, employment and production etc. from primary sources. The information collected from primary and secondary sources has been edited, categorized and arranged in logical order.

The collected data so arranged has been examined with the help of appropriate statistical tools to draw the inherent facts. In analyzing data, simple statistical techniques such as percentage, comparisons, mean and coefficient of correlation has been used to deduce the association among variables, in order to reach conclusions.

5. RESULT AND ANALYSIS

Small scale and cottage industries are no doubt very important for the economy of the state in particular and the economy of India as whole. Recognizing the important role

that small scale industrial sector play in the national economy, both the central and state government have taken active steps to develop, promote and foster their growth. Some of these initiatives have been effective: but most of the problems of SSI still continue to afflict the sector.

6. ENTREPRENEURSHIP

- a) Entrepreneurship can be described as a creative and innovative response to the environment. such responses can take place in any field of social endeavour- business, agriculture, education, social work and the like.

Knowledge about the economic- political environment, more particularly about the economic policies of the government and the financial as well as commercial institutions, is important for the entrepreneur. An entrepreneur is a one who organizes, manages, and assumes the risks of an enterprise who visualizes a business, take bold steps to establish undertaking, coordinates the various factors of production and gives a start.

“Initiatives are underway to promote a culture of innovation based on entrepreneurship which can generate wealth and employment for all citizens.”

Skill India is Empowering workers to become employable. The National Skill Development Corporation(NSDC) is transforming the skill landscape. They drive economic growth and social development of a country. Nations with higher levels and better standards of skilled workforce are able to deal with challenges and opportunities in domestic and global markets.

6.1 GENERAL PROFILE OF ENTREPRENEURS

6.1.1 Year of establishment

The survey shows that majority of the small scale units i.e. 41% in the India were established between 1991 and 2000 followed by 34% in 2000 and 2010, 13% in 2011 and 2012 and 12% before 1990. A tremendous growth has been seen in recent years. Around 46% enterprises have started amongst chosen in last decade say after year 2000.

6.2.2 Types of Organization

There are various types of organization like individual proprietorship, Partnership, Public Limited Company and private Limited Company, cooperatives etc. are found in small scale industrial sector.

Sole proprietorship form of organization is the oldest and most common form of organization for small scale industries. 83% of the respondents owe proprietorship form of organization followed by partnership, cooperatives and Private Sector Company.

Types of Organization

6.3.3 Investment in Plant and machinery

Investment in plant and machinery of an industry indicates its strength. Larger the industry, larger is the size of investment in plant and machinery. Majority of the sample small scale units are having investment in plant and machinery. 55% enterprises invested between 1 to 5 lakhs followed by 51% invested less than 1 lakh.

Investment in Plant and machinery

6.3.4 Size of Employment

Size of Employment

The number of persons working in an industrial concern indicates the overall strength and capacity of the industry. 47% enterprises have six to ten employees followed by 18% eleven to Twenty, 16% up to five, 8% thirty one to forty, 6% forty one to fifty, 3% twenty one to thirty and 2% fifty one and above.

6.3.5 Nature of Operation

Most of the small scale industrial units in the state are operating on perennial basis. Majority (90%) of the small scale industrial units are operating on perennial basis while 10 per cent are operating on seasonal basis. Ice Plants, Brick making units and units which depends on seasonal raw materials for their production like fruit juice units, gur making etc operates on seasonal basis. No casual units found operating within the sample units.

Nature of Operation

6.3.6 Age of Entrepreneur

The age of the entrepreneur plays an important role in the overall growth and expansion of any industrial concern. Innovative spirit, adoption of new methods and techniques of production, progressive outlook, risk taking ability etc. are very closely related to the age of the entrepreneur. 47% entrepreneurs are in the age group of 30 to 40 followed by 28% in the age group of 40 to 50, 16% in the age group of 20 to 30 and 9% in the age group of 50 and above.

Age of Entrepreneur

7. CONCLUSION

It is encouraging the development of SSIs sector as a way to diversify Indian economy. The main purpose of data collection was to study how the entrepreneurs managed the small scale industries and enterprises. What are the various problems faced by these enterprises. It also showed how the role of MSMEs helped in economic restructuring and development of India. Reorientation in the attitude of the people of the state in general, the educated youths and capitalist class in particular is the urgent requirement for paving the way of industrialization in India. People of the state must give up the lure to earn easy money and set their mind to take risk. They should learn from the past. We cannot deny that with “obsession over industrial revolution and liberalization.

This is not at all good for the country. If the small scale sector is to act as an agent of decentralization in rural and sub-urban areas, the government should come forward by making masses aware and strengthen the infrastructure in India. By Establishing more banks to provide loans to start or set up a small scale industrial units for their procurement and fulfillment of resources. Packages of incentives and the inherent talents of India in the form of a big push are required to move the economy on industrialization path and an empirical approach is needed to educate youth must come forward with a new vision and energy to break the vision of non industrialization in India.

Investigation of Existing Hanger Making Process using Work Study

Amruta Adbe, Priya M. Khandekar

Department of Industrial Engineering
Shri Ramdeobaba College of Engineering and Management, Nagpur, Maharashtra, India

Abstract: Method Study is the systematic recording and critical examination of existing and proposed ways of doing work so as to improve productivity. Time study is a work measurement technique for recording the times and rates of working for the elements of a specified job carried out under specified conditions, and for analyzing the data so as to obtain the time necessary for carrying out the job at a defined level of performance. It provides the suitable recording technique to investigate information about existing process so as to improve it. The paper is about the method study and time study conducted at TRADC (Textile Research and Application Development centre), a unit of Grasim Industries Ltd. The main purpose of the study was to improve productivity by standardizing the hanger making process and its time. The study was carried out and improvements were implemented. After the implementation, there was significant time reduction by 23.08% and increase in operator's efficiency thus improving productivity.

Keywords: Efficiency, method study, time study, two handed process chart, workplace layout, productivity.

1. INTRODUCTION

Productivity improvement is the need of current industrial scenario. In industries or manufacturing firms the quantity to be produced is fixed and different techniques are used to improve process effectiveness and productivity. In R&D centers the quantity to be produced is not fixed and depends on the order from the customers. So, in order to improve productivity operator's efficiency is the area to be worked upon. In this paper a case study was carried out at TRADC (Textile Research Application Development Centre) to improve productivity. TRADC is a globally leading R&D centre of the Aditya Birla Group with 12 years of excellence having a vision to facilitate Indian Textile Industry for achieving global leadership by unleashing the power of innovative designs and products for rayon and its blend. Method study was carried at TRADC which in turn resulted with significant time reduction by 23.08% and increase in operator's efficiency by 17.073% thus improving productivity.

2. LITERATURE REVIEW

"Effective utilization of manpower in outside services for manufacturing firm", a case study discussed by **Ajinkya Jadhav**⁽¹⁾ which deals with the work study done using multiple activity chart and six sigma concepts which resulted in significant reduction of time and cost and helped improving operator's efficiency." A case study of productivity improvement by using IE tools", a paper pioneered by **Satish Keru Raut**⁽²⁾ deals with the different charting techniques used in the productivity improvement. It focuses about study being carried out at MAHINDRA for two operations for HINO on BMV 60. This resulted with

reduction in work content and increased operator's efficiency of doing the job." Application of Maynard Operation Sequence Technique – A case study", discussed by **Anuja Pandey**⁽³⁾ which deals with manpower efficiency improvement. The paper is about the improvement in the process effectiveness thus reducing work content and increasing productivity and reduction in operator's fatigue which in turn resulted with the increase in operator's efficiency. "Productivity Improvement by Work Study Technique: A Case on Leather Products Industry of Bangladesh", conferred by **Md.Abdul Moktadir**⁽⁴⁾ which deals with the study being carried out at leather industries. The work and method study as well as work measurement was done mainly focusing on the assembly line section and it resulted in the increase in productivity with the reduction work content by 12.7% thus benefiting the industry in terms of profit." An effort to apply work and time study techniques in a manufacturing unit for enhancing productivity", a paper presented by **Patange Vidyut Chandra**⁽⁵⁾ which is about the systematic approach towards the application of time study and method study. These techniques in turn decrease the work content thus improving the effectiveness and productivity of the process being done. The productivity is related to the work content which in turn deals with the reduction in ineffective time. Ineffective time can be defined as the time which is responsible for the increase in work content which may be due to the ineffective method or improper utilization of input materials and input resources. Ineffective time can be reduced using different techniques available to improve method effectiveness and operator's efficiency. This is

applicable for any manufacturing firm or industry or R&D centre.

3. METHODOLOGY

Based on the literature survey, the following methodology was developed to improve productivity:

- Systematic recording of all information about the existing process using suitable two handed process chart and multiple activity chart using method study.
- Critical examination of the process by questioning each fact that has recorded to develop alternatives and study the workplace.
- Evaluation of alternatives to select economic and easier method of doing work.
- Developing proposed method.
- Determination of standard time using stop-watch time study.
- Defining the final method.

4. CASE STUDY

The method study conducted in TRADC, there is opportunity for improvement in the garmenting department.

4.1 Garmenting Department:

The study was carried out on the hanger making procedure from readily available cut piece of fabric. It was found that the procedure so followed was tiresome for operators. The activity is recorded in the form of two handed process chart. The two-handed process chart is a process chart in which the activities of a worker's hands (or limbs) are recorded in their relationship to one another.

Existing workplace layout:

4.1.1 Two Handed Process Chart (existing):

Left hand activity	●	→	◻	▼	Right hand activity	●	→	◻	▼
Hanger taken					Idle				
Idle					Fabric taken				
Fold is opened					Fabric is inserted				
Stapler is taken					Hold the hanger				
Hold the hanger					Hanger is stapled				
Idle					Stapler is kept back				
Flip the hanger					Flattener taken				
Hold the hanger in flipped position					Stapled pins flattened				
Idle					Flattener kept back				
Idle					Cutter taken				
Hold					Strip removed				
Strip stuck					Strip stuck				
Hanger kept aside					Idle				
Idle					Cutter kept back				
Total	4	2	5	3	Total	5	6	2	1

- **Summary:** Total process time for making single hanger = 67.6sec

Activity No.	LHS	RHS
● Operation	4	5
➔ Transport	2	6
■ Delay	5	2
▼ Hold	3	1
Total	14	14

Proposal:

A method with no delay was proposed to improve operator's efficiency. So the proposed method is:

Proposed workplace layout:

4.1.2 Two Handed Process Chart (proposed):

Left hand activity	●	➔	■	▼	Right hand activity	●	➔	■	▼
Hanger taken from stack	•				Fabric taken from stack	•			
Hanger brought to assembly		•			Fabric brought to assembly		•		
Fold is opened	•				Fabric is inserted	•			
Hold the hanger				•	Stapler brought to assembly			•	
Hanger inserted in stapler gap	•				Fabric stapled into hanger	•			
Hanger taken away from stapler gap	•				Stapler kept back & flattener is taken			•	
Hanger is flipped	•				Stapled pins flattened	•			
Cutter brought to assembly.		•			Flattener is kept back			•	
Hanger is held				•	Strip is removed by cutter	•			
Sticker pasted on staple pins	•				Sticker pasted on staple pins	•			
Hanger kept aside		•			Cutter kept back			•	
Total	6	3	0	2	Total	6	5	0	0

- Summary: Total process time for making single hanger = 52sec

Activity No.	LHS	RHS
● Operation	6	6
➔ Transport	2	5
■ Delay	0	0
▼ Hold	2	0
Total	11	11

- There was a decrease in time by 23.08% after implementation of proposed method.

4.2 Time Study:

Time study is a work measurement technique for recording the times and rates of working for the elements of a specified job carried out under specified conditions, and for analyzing the data so as to obtain the time necessary for carrying out the job at a defined level of performance. Time study was conducted after standardizing the process to

calculate the standard time for the process. The readings were recorded in short time study form. The study was done for single qualified operator. The rating was given by the company personnel and accordingly standard time was calculated. The standard time was calculated using stop watch time study.

Conditions:

Operation – hanger making process

Worker – qualified

Rating – 75%

4.2.1 Time study sheet:

Operation: Hanger making Process						Study no. :1 Sheet no. :1		
Operator: Qualified						Studied By: Amruta Date: 20/06/2017		
Working Conditions: Adequate						Checked by : Mr. Ketan Patel		
No.	Element Description	Observed Time			Total O.T.	Avg. O.T.	Rating	Normal Time
		1	2	3				
1.	Hanger and fabric bought to working area and hanger is being opened.	7.57	10.5	8.67	26.74	8.91	75%	6.68
2.	Fabric inserted	14.5	16	15	45.5	15.16	75%	11.37
3.	Stapler bought to working area and hanger is being stapled.	18.5	18	17.1	53.6	17.87	75%	13.4
4.	Hanger is flipped, stapler is kept back and flattener bought to working area. Stapled pins are flattened.	8	9.56	10.3	27.86	9.29	75%	6.96
5.	Flattener is kept back and cutter is bought to working area and strip is being removed.	4.79	3.8	3.61	12.2	4.07	75%	3.05
6.	Sticker pasted on hanger and the cutter is kept back	3	3.01	2.78	8.79	2.93	75%	2.2
7.	Final hanger kept aside	3.66	3.41	3.51	10.58	3.53	75%	2.65
		Σ			184.72	61.76		46.31

Average Observed time = 61.76 sec

Normal time = Average Observed Time * Rating% = 61.76 * 0.75 = 46.31 sec

Allowances = Personal + contingency allowance = 4+6 = 10%

Standard time = Normal time * (1+ Allowances %) = 46.31 * (1+ 0.10) = 50.941 = 51 sec (approx.)

5. CONCLUSION

Method study is carried out in industries for productivity improvement and product optimization. Time study is carried to standardize process timing. However, from the above findings it can be said that method study and time study can also be applied in R&D centers as it deals with improvement in operator's efficiency of doing work thus reducing time and increasing productivity. So, with reduction in time by 23.08% and increase in operator's efficiency, the working process of R&D becomes more efficient which would help them for new product development.

6. RECCOMENDATIONS

After discussing and arriving at a conclusion the following suggestions could be drawn:

- Proposed workplace layout with tools & equipments pre-positioned.
- Significant reduction in time.
- Increase in operator's efficiency.
- No delay in job.

ACKNOWLEDGEMENT

We sincerely thank to the Head TRADC, Dr.Vijay Ramkrishnan and entire TRADC staff for their cooperation, motivation, and to enhance learning regarding the implementation of work study in R&D centers.

Role of Industry Institute Interaction in Entrepreneurship Development

Dhananjay R. Dolas, Shrikrishna B. Pawar

Department of Mechanical Engineering, MGM's JNEC, Aurangabad, Maharashtra, India

Abstract: The paper aims to identify the requisite measures to be undertaken by an industry and institute in order to engage successfully in entrepreneurship development. The objective of any technical institution is to produce skilled and competent technical professionals through quality technical education and to prepare them for immediate employment in industries. However, with the globalization the past decade has seen a significant change in the requirements of industries. These new requirements demands, technical professional to identify and manage knowledge resources with business potential. Industry institute interaction (I-I-I) can provide best platform to engage industries with technical institute and I-I-I can have significant influence on development of technical students as a future entrepreneurs.

Keywords: Entrepreneurship, Industry, Institute and Students

1. INTRODUCTION

Technical education forms the backbone of progress of any nation. The journey of mutual aid between Industry and Institute has taken different forms at different times. Historically it started with simple interaction and gradually evolved to very close partnership overtime. India has one of the largest technical manpower in the world. But compared to its population, it is not significant and there is a tremendous scope of progress in this area. Bridging the skill gap is the need of the day and decides the national development and economic growth. Patil [1] focused on Industry-Institute Interaction benefits. Faculty members of the institutions should be aware of the various schemes from Government as well as other organizations for skill development and practical trainings. For countries like India, where huge man power resource is available, Institutions should come forward to take active part to grab this opportunity. Jayaprakash and Meenakshi [2] discusses on academic freedom in conducting Industry related research of commercial Entrepreneurs. Therefore Institute-Industry research partnerships should be redirected towards facilitating better research relationship for the welfare of mankind under academic autonomy. Lavanya [3] examine the different modes Industry –Academia Interaction adopted by the colleges and to analyze the student's awareness about the benefits from modes of Industry – Academia interface. By getting understanding in to these insights Academia can further develop the programmes which add more authenticity to the interface. Pai et al. [4] discusses the adoption and operation of curriculum which when taken up in professional colleges may help making of entrepreneurs when the student completes his academic courses. Richard and Gift [5] presented the survey which aimed at establishing the role of industry and commerce in

secondary teacher technical/vocational skills development through ODL.

2. INDUSTRY INSTITUTE INTERACTION

Interaction between industry and institute is increasingly a critical component of efficient innovation systems. Successful interaction between industry and institute supports the objectives of each partner. For institutes, typical objective to interact with industries includes improvement of teaching, development of advanced curriculum, reputation enhancement, and increase in placements. For industries, the motivation to collaborate with institutes includes gaining access to complementary technological knowledge, acquiring fresh talents through campus placements and providing training to existing or future employees.

Institutes are expected to broaden the experiential learning of students and develop the skill sets to match the current requirements of industries. To cope with these expectations institutes are engaging with all stakeholders which also includes industries.

3. CONCEPT OF ENTREPRENEURIAL INSTITUTE

There is empirical evidence that identifying, creating and commercializing intellectual property have become institutional objectives in various academic systems.¹ Technological institutes focusing on teaching, research and also economic development in form of entrepreneurship development. This shift in focus by institutes is majorly because of the influence of external environmental factors and internal factors both. External factor includes increasing competition in technological education sector and an internal factor includes self awareness of institutes towards need of harnessing potential of ecosystem.

Entrepreneurial institute concept focus on development of personal skill, attributes, behavioral and motivational capacities of students to facilitate application of these enterprising skills to start new venture or innovate in existing enterprises. Entrepreneurial institute not necessarily focus on setting up of profit organizations but equally applicable in the context of nonprofit organizations and social enterprises also.

However many academics and others view the entrepreneurial paradigm as a threat to the traditional integrity of the universities.² But it is evident from the examples of developed countries that role of technical institutes with entrepreneurial focus fosters technological innovation systems which leads to the path of economic development.

4. KEY CHALLENGES IN ENTREPRENEURSHIP DEVELOPMENT

Many technical institutes establishes entrepreneurship development (ED) cell with objective to help students in practicing entrepreneurship. Non premium and self funded technical institutes faces greater barriers in achieving the objectives of ED cells. Key challenges in development of entrepreneurship practice include

Fig. 1. Key challenge in ED

- 1) **Motivating students to take entrepreneurship as a career option:** The principal challenge before ED cells lies in motivating students to consider entrepreneurship as a career option and thereafter encouraging them to execute their business ideas in reality.
- 2) **Provision of good mentoring:** Another challenge lies in supporting students of enterprising mindset by a good mentor. Proper mentoring helps in smooth the progress of setting up startups and also facilitates networking with potential business partners and clients throughout the various phases of startups.
- 3) **Facilitation of timely seed funding:** Another main challenge in attaining goals of institute lies in

unavailability of seed funding for young students. Unlike developed countries, entrepreneurs in India face greater barriers in managing the seed fund for their business ideas because of less number of angel investors and venture capitalists are available in the country.

5. ROLE OF I-I-I IN ADDRESSING KEY CHALLENGES IN ED:

Engagement between industries and academia is critical for promotion of entrepreneurship among students. This engagement can expand the relevance of academic research carried out by students and faculties and foster commercialization of outcome of these research work. Developed countries are reaping the benefits from such engagements.

TABLE 1: Summary of I-I-I Measures to address key challenges in ED

Sr. No.	Key challenge	Measures by I-I-I
1	Lack of motivation to consider entrepreneurship as a career option	Training the trainers and implement entrepreneurial curricula
2	Unavailability of professional mentoring	Combining the experience of mentors with eagerness to thrive of students
3	Poor access to seed fund	Common commercialization of innovation through systemic approach

1) Training the trainer:

Industries can enhance the academic environment by addressing the barrier of lack of inspiration for students to practice entrepreneurship by motivating them through lectures or discussion sessions. Industries can also initiate the concept of training the trainers to build the capacity of teacher to inculcate the entrepreneurship skills among students. The collaborative relationship of industry and institute can spearhead the development and implementation of entrepreneurship curricula in the technical education sector.

2) Proper mentoring to start, restart and reduce failure stigma:

Students of this age are likely to have more ideas as they are to be considered as born digital and they are also taking advantages of increased learning opportunities available. Such students can be benefited a lot from well planned and implemented industrial mentoring programs. It is evident from the examples of Spanish universities that availability

of mentor can be a career impulse for students as it allowed them to seek personal guidance from mentor which can facilitate the smooth implementation of business projects. Positively build relationship between industrial mentor and academic student can address the challenge of networking for budding entrepreneur. Institute can foster the entrepreneurship by synergizing the entrepreneurial talent of students and professional guidance from industrial mentors.

Mentoring can increase the confidence and self esteem of students which minimizes the stigma surrounding the business failures and encourages the restarting.

3) Access to funding:

Industry and institute can take leadership role in promoting innovation by providing incentives that will encourage students to develop and apply competencies and skill set to exploit technology to create commercialized products and services.

Entrepreneurial development is about developing an innovation system but India is categorized in the group of countries having investment in R and D sector less than 1% of its GDP. Integration of research efforts to create intellectual property, innovative products and services is much weaker in India as compared to that of developed countries. This can be treated as opportunity by industry and institute to recognize the need of the holistic and systemic approach to formulating entrepreneurship financing policies. To attain the objective of sustainable development through entrepreneurship, timely availability of seed funding is critical.

Provision of innovation fund, technology transfer office and incubation centers can be instrumental in spurring early stage entrepreneurship through common commercialization of innovations between industry, institute and budding entrepreneurs.

6. CONCLUSION

The importance of entrepreneurship in the context of sustainable development through job creation, economic growth highlights the need for comprehensive framework

for the promotion of entrepreneurship development and calls upon the relevant organizations like industries and technical institutes in coordination of initiatives to facilitate entrepreneurship. Measures initiated by I-I-I can address the challenges related to fostering ED and facilitate systematic approach in attainment of goal of technical institute to develop students as a successful entrepreneur.

Industries and Institutes have been collaborating for over a century, but the rise of a global knowledge economy has intensified the need for strategic partnerships. The Institutes are imparting the basic knowledge and skill, but the Industry-Institute-Interaction will enable to undertake research by staff and students relevant to the Industry. The Industry-Institute-Interaction should be designed to run longer period for preparing the manpower of world class in the field of science and technology by inculcating the various skills required by the industry and thereby contributing to the economical and social development at large.

Employee Welfare Activities- A Case Study of Hari Krishna Exports Pvt. Ltd.

Pratha Jhala

Department of Business and Industrial Management,
Veer Narmad South Gujarat University, Surat, Gujarat, India

Abstract: Cutting and polishing diamond industry is a labour intensive industry, which is highly dependent on skilled labour force along with technologies. To increase productivity in such labour intensive industry one has to boost up worker's motivation. One way of facilitating motivation of workers is through labour welfare activities. This paper makes an attempt to study welfare measures and satisfaction level of diamond polishers towards employee welfare activities at the cutting and polishing units of Hari Krishna Exports Pvt. Ltd. As stated in to an Oxford Dictionary, welfare activities aim at making life worth living for worker. Labour welfare can be classified into statutory and non-statutory welfare measures. In this paper emphasis is given more on non-statutory welfare measures as it distinguishes the organization from other in terms of welfare measures adopted by it. For this purpose primary study of diamond polishers of the organization through a structured questionnaire and an in-depth interview of management has been done.

Key words: Employee Welfare, Employee Satisfaction, Diamond Industry.

1. INTRODUCTION

1.1 Employee Welfare

“Employee” or “Labour” is most crucial Factor of production, when it comes to make them work efficiently and effectively. Unlike other Factors of production, they have both mind and heart. To increase productivity of an organization, employees must be motivated to work with their heart and mind both. One way of facilitating motivation of workers is through employee welfare activities.

The Oxford Dictionary defines employee welfare as “efforts to make life worth living for worker.” While The [International Labour Organization] ILO at its Asian Regional Conference, defined labour welfare as a term which is understood to include such services, facilities and amenities as may be established in or in the vicinity of undertakings to enable the persons employed in them to perform their work in healthy, congenial surroundings and to provide them with amenities conducive to good health and high morale.

Moorthy (1968) has described two types of welfare in his book “Principles of labour welfare.” He has grouped welfare activities as welfare measures inside the work place and welfare measures outside the workplace. Welfare activities can be categorized as intra-mural facilities and extra-mural facilities. Intra-mural facilities include those facilities, which are provided within the factories while extra-mural facilities are those facilities, which are provided outside the factory. (Aswathappa)

It can also be classified as statutory and non-statutory activities. Statutory provisions are made mandatory by government by imposing laws such as, Factories act, 1948; The Mines Act, 1952 for the workers working in mines; the Plantation Labour act, 1951 for plantation workers; The Motor Transportation Workers Act, 1961 for motor transport workers; The Contract Labour (Regulation and Abolition) Act, 1970 for welfare and health measures of contract workers; The Merchant Shipping Act, 1958 that covers welfare measures of seamen. Dock Workers scheme, 1961 for the safety, health and welfare of workers working on the dock. Non-statutory benefits are those benefits that are done voluntarily by the company such as, loans for house, education of children, sports activities, entertainment activities, transportation facilities etc.

Employee Welfare Measures are justified because of some reasons. It helps in motivating employees, retaining employees, developing loyalty, minimizing social evils, improving company image, helps in cutting down labour turnover and makes employees happy, cheerful and confident looking. (Aswathappa) Employee Welfare Measures also improves efficiency, builds competitive advantage for the company, improves industrial relations, attracts more employees, urges employees to work better and induces them to work harder. (Reddy)

1.2 Hari Krishna Exports

Hari Krishna Exports, known as HK exports is a leading diamond manufacturing and exporting unit established in the year 1992 by Mr. Savaji Dholakia and his three brothers. The company is having two manufacturing units

in Surat where 5700 employees are working. One unit is at Simada gaam, varaccha, while the other unit is situated at Gems & Jewellery Park, Icchapore. Total turnover of the company has reached to 6000 crore rupees. Yearly production of the company is 10, 00, 000 carats diamonds. Company has business operations in more than 75 countries.

Mr. Dholakia who him self is not having education of primary schooling too; gives credit of success to his workers, whom he calls “diamond engineers.” He compares them with engineers as to cut and polish a diamond; they need to work very minutely with minimum mistakes as it a very precious commodity. The company follows highly employee-oriented philosophy. Here average salary of a diamond polisher is 58, 000 per month while average education is up to 10th standard only.

Savajibhai says, “we are not only giving salary but love to the employees.” He believes that by giving more, employees will feel accountable and will become more responsible. So by giving more the company is gaining more. He believes that in his factory he does not make diamonds but makes “Humans”.To concur his thoughts into the reality he personally looks into the welfare of the employees. Company spends 5% of the net profit on employee welfare activities every year. Some of the welfare Measures are so unique that it differentiates the organization from others into the industry such as distributing cars, homes or jewelry among employees as Diwali bonus. This made big news countrywide and it motivated the researcher to study other welfare measures provided by the company too.

2. REVIEW OF LITRETURE

Shivakumar (2008) has examined business practices of Jamshedji Tata with context to stake holder’s welfare. The article also examines employee welfare activities considered by Jamshedji Tata, which shows importance given to the welfare activities in nineties too.

The researches have been done in various industries for instance, Tiwari (2014) has studied employee welfare activies at Vindha telelinks Ltd. Jain and Goel (2014) have identified satisfaction level toward employee welfare activities in banking sector. Dr. Nair and Jha (2017) have studies employee welfare programmes in IT industry. Salaria & Salaria (2013) have studied welfare measures in auto sector. Ramya, Bhavashree and Dr. Lakshmi (2016) have studies welfare measured in hotel industry.

Qadeer and Roy (1989) have studied about the work, wealth and health of Indian workers in industrial sectors. A vast data was collected from the data published by the Labour Bureau of the Ministry of Labour and Employment, and information on industries of a district in Madhya Pradesh-Shahdol-and its surrounding areas and found that labour

unions had more concentrated on compensation and not on health and safety measures.

Jebamalairaja and pichumani (2012) have done research in this area on secondary database and have found that Labour welfare measures are grossly inadequate in India when compare to international standards. After visiting units of HK Exports it was clearly observed that the organization is not lacking behind in any terms where it comes to labour welfare.

Madhuri (1978) has studied in the article “Outlook on employee welfare cost” non-wage benefits from the view of management, Unions and employees in 16 manufacturing units of Mumbai.

3. OBJECTIVES OF THE STUDY

To study various statutory and non-statutory welfare measures adopted by HK exports Pvt. Ltd.

To study satisfaction level of diamond polishers towards these welfare measures.

4. RESEARCH METHODOLOGY

To study welfare measures and satisfaction level of employees towards employee welfare activities at Hari Krishna Exports Pvt. Ltd, secondary data was collected from the journals, articles, management books and websites. Primary data was collected through a structured questionnaire and in depth interviews with top management. Samplesize of 100 workers was selected through non-probability convenience sampling.

5. MAJOR FINDINGS

Statutory and Non-statutory welfare measuresat Hare Krishna Export Pvt. Ltd. and satisfaction level of workers towards it.

- At factory premises basic facilities are provided such as purified drinking water and toilets. 94 Percent employees are highly satisfied with drinking water facility. 66 Percent employees are highly satisfied with toilets while rests of employees think cleanliness should be improved regarding to the toilets.
- Canteen facilities are available where all 5700 employees take their lunch free of cost. 76 percent employees are highly satisfied with food and canteen facility while 20 percent are satisfied with it.
- Working hours are 9 hours a days including a lunch break. For this 88 Percent employees are highly satisfied, as they don’t need to do overtime except at Diwali time.
- Two paid vacations out of which summer vacation for 10 days and Diwali vacation for 20 days are given. Festival holidays are also given. 94 percent workers are highly satisfied regarding this.

Fig. 1. Satisfaction level of employees towards various welfare measures at HK Exports Pvt. Ltd.

- Uniforms are distributed in adequate amount to all the employees. 98 percent employees are highly satisfied with adequacy of uniforms.
 - Transportation facility is available free of cost to the employees who wants to avail it. For that 96 percent employees are highly satisfied.
 - The work place is centrally air-conditioned with enough lighting and comfortable seating arrangements. Massage chairs are also available for employees who want to get relaxed during working hours. 90 percent with overall working condition, 92 percent with seating arrangements, 90 percent with proper lighting and 84 percent employees for overall working condition are highly satisfied.
 - Health and Safety measures
 - There is a clinic and an ambulance, which is available at the factory 24X7 for any emergency in case.
 - Every employee is insured against medical insurance. Employees with tenure of more than five years are having death insurance worth 10 Million INR.
 - Play grounds for out door games such as cricket, volleyball, swimming is there at company premises so that employees can maintain their physical health as well as they can get relax after work.
- Indoor games facilities are also available.
 - Company is having its gym where employees can come for exercising and can lead to a healthy life.
 - For mental health and relaxation the organization sends employees to 11 days workshop of “vipasyana”, that is meditation. Company bears all the expense of this program.
 - For the safety of employees it is compulsory to wear helmet while driving two-wheeler or they won’t be allowed to enter the company campus.
 - Strictly prohibition of chewing tobacco or smoking into the work premises or outside the work premises. This step has prevented many employees from the addiction of tobacco and smoking.
 - Company organizes blood donation camps and seminars on thalassemia and AIDS to spread awareness. Free compulsory check ups for the thalassemia are also conducted.
 - To encourage employees to take part in marathon company pays for those employees who volunteer

to be the part of marathon organized by local bodies. Around 4000 employees participate in this event.

- 90 percent employees are highly satisfied with basic medical facilities. For insurance 86 percent employees are highly satisfied. 92 percent employees are highly satisfied with social messages regarding tobacco and helmets. 70 percent employees are highly satisfied with medical camps and checkups. Here percentage is comparative law as being law in educational qualification they are not aware about the significance of these checkups.

➤ Educational facilities

- Employees: especially diamond polishers in the diamond industry are not much educated, but to make sure that their children gets education, company offers to pay fees for their children.
- For Gujarati medium, company pays yearly 3000 INR for nursery, 4000 INR for primary education, 5000 INR for secondary and higher secondary education and 6000 INR for graduation and post graduation.
- To encourage the employees to give their children education in English medium company pays yearly 7000 INR for nursery, 8000 INR for primary education, 9000 INR for secondary and higher secondary education and 10, 000 INR for graduation and post graduation.
- More ever, notebooks are also distributed to the children of employees.
- Various seminars on parenting and childcare also conducted by the organization for awareness.
- 84 percent employees are highly satisfied with these educational facilities.

➤ Recreational facilities

- The company organizes religious tours every year for employees and for their parents, once in every 3 years.
- The company for the entertainment of the employees also organizes various cultural programs such as shows for plays, Navratri functions, and movie days.
- To motivate employees slogans and inspirational thoughts are written on the walls in local language.

- 88 percent employees are highly satisfied with the facilities they enjoyed on tours and 92 percent for other recreational facilities such as entertainment facilities.

➤ One Step ahead

The organization also does some unique welfare activities that are rare.

- HK diamonds distributes houses, cars and diamond jewelry to the workers as Diwali bonus according to their set standards of performance. Up till now 2900 workers are benefited from this scheme. The bonus is given as per their performance against set standards. The company does fulfillment of down payment or EMIs as per the requirement and performance of the employees. On inquiring about would they prefer cash to these benefits; they replied that they are being paid enough salary so these kinds of benefits are more useful to them. The organization distributes cars or houses or jewelry as per the necessity of the workers. Mr. Dholakia is having a dream that every employee should have all these facilities when he retires from the organization.
- They also arrange for weddings of the sons and daughters of employees, where company bears whole cost of wedding. In 2014-30, in 2015-66 and in 2016-53 such marriages were organized and sponsored by the company.

6. CONCLUSION

Employee welfare measures are vital to any organization as this leads to many benefits to the organization. Welfare Measures that are imposed by the Law are Statutory Welfare Measures. But when it comes to Non-statutory Welfare Measures, it is totally up to the culture of the organization and philosophy of the management. As research has demonstrated, the organizational culture of Hare Krishna Pvt. Ltd. is "Employee Oriented." Some of the welfare measures such as distribution of bonus at the time of Diwali, funding weddings of the children of employees, religious tours for parents of the employees are unique; as these activities are not only for the employees but also for their families too. Here the satisfaction level of employees towards welfare measures is very high. The organization truly provides an inspirational model to other organizations for Employee Welfare Measures.

Environmental Impact of Tourism on Vembanad Lake

Joseph Chandy, Raghunathan Rajesh

Department of Mechanical Engineering,
Rajiv Gandhi Institute of Technology, Kottayam, Kerala, India

Abstract: Vembanad wetland is the largest wetland system in India which is the official site of the Ramsar convention on Wetlands. Human intervention on the lake is severe which affects the function, structure and entire composition of the Vembanad wetland system. There is a drastic growth in tourism sector in and around Vembanadu Lake for the past two decades. This paper focuses on the impact of tourism on Vembanad lake system and also to the environment. As a result of the tremendous growth of Backwater tourism in and around the Vembanad Lake, the waste composition has increased to a large extent. The major waste from tourism sector was identified through a questionnaire survey, on the peoples residing near the lake and these waste were quantified through different methods. The performance evaluation of the existing waste management system was conducted and found to be ineffective. Since a lack of a proper waste management system, this paper aims to propose a modified waste management system which is economically and socially beneficial. The economic analysis was done by conducting cost benefit analysis to the 4 alternatives and the existing system. These four alternatives were designed within the framework of the modified waste management system. The payback period of these alternatives and existing model were calculated and based on this, the most economical and social waste management system was proposed

Keywords: backwater tourism, performance evaluation, waste management, cost benefit analysis, paybackperiod

1. INTRODUCTION

Vembanadu Lake spreads in Alappuzha, Kottayam and Ernakulum districts of Kerala which forms Vembanad Lake wetland system of an area of 2033.02km². In the past twenty years the growth of tourism sector in and around the Vembanad Lake is spectacular. Backwater tourism as emerged as the backbone of the tourism sector of Kerala state which leads to the tremendous increase of Houseboats in addition to many resorts which developed recently around the shore of lake. Kerala comes under the list of 50 places of Life time published by National Geographic Traveler scenic beauty of the region attracts the domestic as well as the foreign tourists. Kuttanad wetland system including Vembanad Lake which is now receiving global attention because of its unique feature which is below sea level permits the cropping of Rice in large quantity and permits the harvest of fish and an area which is thriving for the tourism where the nature beauty is at the peak among the Ramsar site.

Percentage of increase of foreign exchange earnings from tourism in Kerala in last decade is 68.9%. Rise of tourism sector results into shift of employment, one or two member from each house is now engaged in tourism industry as houseboat operators or other employment related to house boat and backwater tourism. This shift in employment sector from agricultural to the service sector is caused as a result of change in attitude and perception to the traditional occupation like agriculture. Shift of employment itself indirectly effects the agricultural production of the region. Uncontrolled growth in the number of the houseboat in Vembanadu wetland system affects the environment system

of lake. This project focuses on the adverse effect of the backwater tourism growth on the environment system of wetland and livelihood of the area around the lake and to find out a proper waste management system in the region.

2. LITERATURE REVIEW

There has been an ample amount of literature in the domains of tourism and its causative factors from various studies conducted around the globe. Many of them are based on different aspects. By looking through the literature in environmental impact of tourism the commonality observed in the existing literature is that tourism can affect Socio-cultural of host community which includes changes in traditional lifestyles, value systems, family relationships, individual behavior and community structure. Even though the tourism sector in the region has greater economic benefits which are employment income and foreign generations there are also negative socioenvironmental impacts (Zacharias and Manalel, 2010). Tourism development can be of benefit (e.g., job creation, image enhancement). However, it could also have negative impacts on the biophysical environment (e.g., soil pollution, water pollution, air pollution, ecosystem degradation) and social/cultural environment (e.g., loss of the traditional culture, increase in crime) if not well planned, developed, and managed (Mohammad, 2016). In another one the impacts of tourism on environmental attributes such coral reefs, water, fisheries and beaches are discussed briefly. The impacts of tourism towards environmental attributes range derives from tourism activities such as boating, snorkeling, diving and fishing. Improper and irresponsible behavior of tourist is also believed to be a significant reason

that contributes to detrimental effects on the environmental attributes (Murugadas and Badaruddin, 2014). The different mind-set of tourist derives from the different level of environmental literacy that they have. The concept environmental literacy that consists of not only knowledge on the environment and its issues but also includes disposition components of attitudes, sensitivity and motivation are discussed thoroughly. Intention to act or intended behaviour that is explored in this (Ferry, Lucky, Dietrich and LilikBudi, 2016). The link between the number of threatened plant species and tourism which was proxies by the number of international tourist arrivals (Muzafar and Radamd, 2016),). Tourism has been an important sector to both the developed and the developing economies. Although we recognized the great benefits of the tourism sector to the national income, the tourism activities have also been connected to the negative impact on the economy in particular to the environment. One crucial aspect of the negative impact as a result of increased tourism activities are on the loss of biodiversity. Tourism has an adverse effect on the environment in Eastern EU. Finally, short-run heterogeneous panel causality test results suggest that tourism, causes CO₂ emissions in Eastern EU while economic growth and CO₂ emissions cause tourism in Western EU. Overall, findings suggest that tourism plays an important role in accelerating economic growth however; its role on CO₂ emissions largely depends on the adaptation of sustainable tourism policies and efficient management (Alexandra, Christos, Nicolas, Dimitra, 2015).

On the other hand, protected riverside area can make rivers as a source of water, water transport and water tourism destination. Nowadays, water tourism is increasingly popular to people. Local residents should be given an understanding of the importance of tourism activities mainly based on the river environment and things that need to be done to support these activities. River cleanliness must be maintained and preserved (Tri Rahayuningsiha. Hariri and Lilik, 2016) Another one puts forward a generic methodological scheme, based on Life Cycle Assessment (LCA) principles, in order to estimate the environmental load in areas of considerable tourism activity. A comparative assessment is realized for characteristic hotel categories. Their respective contribution to environmental burden attributed to tourists' transport and accommodation services is assessed. Up-market hotels impose larger absolute impacts on the environment, especially in the consumption of resources. LCA can play a crucial role in decreasing the complexity in the strategic planning of tourism, especially in local-to-regional areas of concentrated tourism activities (Orkut and Murat, 2014) Tourism is being considered as a development instrument in order to boost a country's economy and has become part of the global industry. However, tourism is also one of the actors that is responsible for environmental depletion, due

to the constructions of buildings and tourism activities(Hsin and Shiann, 2013)

3. METHODOLOGY

Research is a process of arriving at an appropriate solution to a problem through a systematic approach. This systematic approach will be obtained through a well-defined research methodology. In this project the methodology involves three phases. In phase-1, the problem was identified through a clear background study. After the problem identification a detailed literature survey is a need to define the problem. From the problem definition, the main objectives of the project were determined. As the first step the different types of waste generated from tourism, that affect the Vembanadu Lake was identified. In phase -2 the major waste from the generated waste should be identified. For this a questionnaire survey was conducted and the data was collected from the people residing near the shores of the Vembanadu Lake. In this phase the most predominant waste was determined and was estimated. In phase -3 the existing waste management for the major waste was studied and the performance evaluation was conducted. Based on the evaluation, modification was done to the existing waste management system. Different alternatives were identified and conducted a cost benefit analysis, to find out the best alternative in the waste management

4. RESULTS AND DISCUSSIONS

Rapid increase in house boats, hotels and resorts due to the fast growing back water tourism in Vembanadu Lake causes a tremendous increase in waste generation. Hence there is a lack effective of waste management system in Kumarakom. The main objectives were to identify and estimate the amount of major waste generated from tourism which affects the Vembanad Lake, to conduct a performance evaluation of the existing waste management system and to modify the existing system and conduct cost benefit analysis.

4.1 Questionnaire Survey

A questionnaire survey was conducted as part of the study to understand the major waste from the listed ones and to evaluate about the existing waste management system. The questionnaire consists of 29 questions, out of which first 27 questions were using five scale and these questions were used to measure the effects of each waste components. 28 and 29 were used for rating the waste components for identifying the major waste. The survey was done with the people residing near Vembanadu Lake. Major waste generated from tourism was identified. Survey was conducted with 180 people residing in a stretch of 30km length and a width of 2km from the lake. The sampling technique used is area surveying. 3 respondents from 1Km² area are selected. The number of household units who

participated in the survey was 180. The respondents were approached individually at their homes to get their responses [3]. The major findings from the survey include different negative impacts of tourism and focus on the waste generation. By the help of this survey, it has being identified that sewage from house boats, resorts and hotels and plastic waste dumped in boat jetties and small tourist spot are the major waste from tourism.

4.2 Quantification Of Major Waste

The major waste from tourism is found to be sewage and plastic waste from houseboats, resorts and hotels. The quantity of waste generated from tourism is identified. The unavailability of pre-determined data of amount sewage and plastic generated was a limitation. So the quantification was a big task. The average estimation of waste generated was calculated by conducting a survey and field visits. Sewage from house boat is treated at DTPC sewage treatment plant and the sewage from resorts and the hotels is treated in their own plant. The quantity of sewage treated from house boats was obtained from DTPC sewage treatment log book, but the amount treated in resorts and hotels was not obtained, because they won't keep any records. Estimation of sewage is given below. Kumarakom, 103 registered house boats are there, as per the records given by the DTPC. The maximum amount of sewage is treated at the months of December and

January. From the data an average of 65, 520 litre of sewage is treated in every month.

To identify the amount of plastic waste generated in a month we conducted a survey and field visit to selected tourist spot. The survey was conducted for five consecutive days, at three times a day to get the exact amount of plastic items are dumped in six different spots. Table I shows the mean of the amount of plastic waste generated from the six tourist spot in Kumarakom, for five consecutive days. The plastic waste we are considering are drinking water bottles, soft drink bottles, ice cream cups, plastic glass, are the main plastic waste in these tourist spot.

From the survey the amount of plastic waste generated from hotels and resorts was calculated. In a month approximately 4, 665 kg of plastic is generated from the hotels and resorts in Kumarakom. It's just an approximate amount, this can vary on seasons. From the 21 resorts and hotels these quantities of plastic waste is generated. In this we are considering only on drinking water bottles of 1 litre and ½ litre. In addition to these many other type of plastic waste can be generated such as ice-cream cups, plastic bags, and soft drink bottles so on. This waste can't be estimated due practical difficulties. Annually the least amount of plastic generated will be 55, 985 kg from hotels and resorts

TABLE 1: Quantity of main plastic waste generated at different tourist spot

Sources	Unit	Wt./No.	Mean Total(No:s)	Mean Wgt(Kg)
Water Bottles	No.s	27.98	112.2	3.13
Soft drink bottles	No.s	30.25	94.8	2.86
Ice-cream cups	No.s	5.97	73	0.435

4.3 Performance Evaluation Of The Existing Waste Management System

The major waste from tourism are found to be sewage and plastic waste from houseboats, resorts and hotels. The present system of waste management in Kumarakom is not very efficient. The only way of treatment is done for sewage. The sewage from the hotels are treated in their own treatment plants. Most of the resorts and hotels have treatment plant. The sewage from house boats are treated in sewage treatment plant in DTPC, from the data obtained it is also ineffective. Out of the 103 registered house boats, only 70 of them is undergoing sewage treatment from the plant at DTPC. They are charging a minimum amount of Rs.1250/- monthly from these house boats. The existing system has a cash inflow of Rs.1, 26, 500/- and has a payback period of 10.5 years. In the case of plastic waste there is no proper segregation from the panchayat or from the DTPC Kumarakom. The plastic waste are simply dumped in open spaces and also near the shore of the Vembanadu Lake. These waste are collected by some

unauthorized people daily. There are a limited number of waste bins are situated at different locations. Most of these plastic waste are dumped in open spaces.

The performance of the waste management system in Kumarakom was also evaluated in the questionnaire survey. The questionnaire survey also consists of questions about the management of waste and the satisfaction of people towards the waste management. Out of 180 respondents, 73% of the respondents say that sewage treatment is ineffective and also 67.2% strongly agree that waste management system in Kumarakom is no properly managed. 69 %of respondents stated that cleaning is very important because their no collection or segregation process is taking place.

4.4 Modification of the Existing Waste Management System

The present waste management system in kumarakom has to be modified. From the performance evaluation of the

existing system there should be proper way of collection and segregation of the waste. Sewage from house boats should be collected by some water transport and some fees should be collected from the house boats for treating the sewage, since most of the hotels have sewage treatment plant their isn't necessity of collecting sewage from the resorts and hotels .Since there isn't a proper management of plastic waste, the collection and segregation is also important .the establishment of collection bins at different spots are important for collection. These waste are should be collected by worker and to be segregated in a collection center and to be sold to get some benefit. This system has social benefit than economic benefit. The modified waste management system focuses only on two pre-dominant waste i.e. Plastic and sewage.by the questionnaire survey it has being already stated. he above frame work is used for modifying the existing waste management system. Here the

sewage from the resorts, hotels and house boats are collected and then transported to the treatment plant. The treated sewage is flowed out to the Vembanadu Lake. Similarly the plastic waste from resorts, hotels and from other tourist spot should be collected accordingly and transported and segregated at suitable collection centre. This frame work will help to reduce the effects of plastics and sewage. Within this frame work we implementing four models. Since this is a social issue, it has more social benefit than economic benefit. In this project we are dealing with four alternatives models from this frame work. For deciding the best alternatives we are conducting a cost benefit analysis for each alternatives. These alternatives will be made from this frame work. The implementation of this modified waste management system has both social and economic benefit.

Fig. 1. Modified Frame work of the waste managemen System

4.5 Pay Back Period

The payback period can be calculated. For computing the payback period the fixed investment required for every model and cash flows from that model have to be calculated. For calculating fixed cost of alternative models the expenses related to machinery and other pre-operative expenses are estimated. Next step was to calculate the variable costs associated with different models. This calculation not only helps in DPP but also it will provide an

idea about working capital requirements. Here the variable costs involves, labor payments, utilities paymentsand maintenance costs.After calculating the variable costs the total revenue that can be obtained from the models are calculated considering the price of outputs from the model. This total revenue is subtracted with current revenue to find out the additional revenue obtained from the models. Additional revenue is further subtracted with variable cost to calculate the additional cash inflow per year for a models.

TABLE 2: Cost Benefit Analysis for Different alternatives

Model	A	B	C	D	E
Existing model	13, 30, 000	9, 23, 500	10, 50, 000	1, 26, 500	10.5
Alternative-1	Nil	Nil	Nil	Nil	Nil
Alternative -2	28, 46, 000	29, 16, 900	34, 51, 102	5, 34, 112	5.5
Alternative -3	38, 31, 000	33, 12, 900	28, 39, 893	Nil	infinite
Alternative-4	37, 15, 500	29, 96, 000	31, 42, 102	5, 46, 012	7.5

A-Total Fixed investment B-Variable cost per year C- Total revenue
D-Cash inflow E- Payback Period

Mathematically Fixed cost (A) = cost of machinery + installation charges Variable cost (B) = labor payments+ utilities payments+ maintenance costs Total revenue(C) = Sum of revenues obtained from all output products from the alternative Cash inflow per year (D) = Total revenue – Variable cost Pay Back Period (E) = Fixed Cost/Cash inflow All of these parameters for different models are calculated and the results are as shown in table –II. By conducting the cost benefit analysis for each alternative, the best alternative was found to be the second alternative.in this case the payback period was found to be 5.5 years. In these alternatives the sewage is not collected but these are directly treated from transporting the sewage from the house boat to the tank. In this the number of house boat treated should be noted, the first and the third alternative can't be implement because the total variable cost is more than the total revenue. The fourth alternative has a payback period of 7.5 years. In this alternative the collection is done properly as compared to the fourth alternatives. For an effective waste management the fourth alternative will be selected, because it provides both social and economic benefits. When compared to existing model, collection of sewage and plastic waste was not done.

5. CONCLUSION

Even though the tourism sector in the region has greater economic benefits which are employment income and foreign generations there are also negative socio-environmental impacts. To understand these impacts to the environment of the Vembanadu Lake and to find an action plan is a need to the society. To understand these impacts a questionnaire survey can be done. For this a questionnaire was developed on the basis of the sources which affect the environment. The predominant waste from tourism were identified through detailed literature survey, field visits and also by conducting a questionnaire survey. By studying the existing waste management system in Kumarakom, it was found to be in efficient. A modified system was proposed for the proper management of waste. A frame work was suggested for this purpose, which mainly include collection and transportation. Within this frame work four different

alternatives were made. The four alternatives were proposed, on looking forward the social and economic benefit of these different system to the environment and to the society. The decision of finding the best alternative was done, by conducting cost benefit analysis.Since this is a social issue we have certain limitations for making the profit.

Response Spectrum Analysis for Optimized Building Configuration on Hills in Severe Seismic Zone

Tejaswini S. Junghare¹, Kshitija N. Kadam²

¹Department of Civil Engineering, P. R. Pote (Patil) College of Engineering & Management, Amravati, Maharashtra, India.

²Department of Applied Mechnaics, Government College of Engineering, Amravati, Maharashtra, India

Abstract: Improvement in tourist places contributes to the economical growth of country especially northern region in India which is the most visited tourist places in Himachal Pradesh lies in seismic zone IV and V. Development of those regions impact majorly on overall attraction of tourists. But due to topography of India, northern region is covered with mountains and due to developing cities and urbanization with increase in population construction are carried out on hills. This makes structure unsymmetrical due to slope of ground. This paper studies the dynamic response of step back building with different configuration provided with set back and various bracing system to different heights of building in terms of storey drift, base shear and fundamental time period. All sixteen models are analyzed for dynamic analysis by response spectrum method in structural STAAD Pro. software. The performed analysis conclude with the optimized building configuration on hill slope.

Keywords: Step back building, storey drift, base shear, fundamental time period, optimized building configuration.

1. INTRODUCTION

Development of desired place in Himalayan region of country contributes to originate the economy of such regions due to influx of tourists along with rapid urbanization and highly increase in population. However, due to scarcity of flat terrain or plain lands in hilly areas, buildings are constructed on hills or sloping grounds in those regions. Structural performance of buildings on hills is different than buildings on plain ground. Buildings on slopes are generally constructed as Step back buildings and can be combination of step back and set back buildings. Structures on slope are unsymmetrical which develops torsional moments in structures and cannot resist lateral forces due to eccentricity caused by difference in center of mass and stiffness of each floor. Earthquake forces are lateral forces and the entire Himalayan belt is susceptible to great earthquakes of magnitude more than 8.0. During such high intensity earthquakes, step back buildings attracts more lateral force towards the short column and due to torsional moments, short column fails first and structural stability of building gets disturbed.

Fig. 1. Short column effect

To improve the performance of such buildings on hills or on slope many researches were carried out. Birajdar and Nalawade performed analysis on 24 building models of three configurations by response spectrum method and incorporate that the failure occurs in buildings on slope as a result of short column effect. Zaid Mohammad et.al studied different configuration of step back building and step back & set back building and suggest most suitable configuration for buildings on slope in earthquake prone areas. Nagargoje and Sable presented seismic analysis on step back building, Step back and set back building and set back building. The work shows the comparative study of three configuration with respect to the parameters as base shear, top storey displacement, store drift etc. Kalsulkar and Rathod analyzed the building of step back frames and step back-set back frames on various sloping ground for zone III. This study states, step back-set back frames gives least values of time period and base shear, the performance of step back frames proves more vulnerable than step back-set back frames and suggested for special attention while designing short columns. Y. Singh et.al highlighted on seismic behavior of hill building during the Sikkim earthquake of September 18, 2011. Analytical investigation carried out to know dynamic response of hill buildings comparing with regular buildings on flat ground in terms of fundamental time period of vibration, inter-storey drift, column shear etc. Hirde & Shelar and Junghare & Shinde studied on positioning of RC shear walls and bracing system for seismic analysis on buildings resting on sloping ground. Represents results in terms of parameters as base shear, lateral displacement, time period and member forces.

Many analysis are carried out to study the performance of structures on slope. To improve performance of step back

buildings during earthquake various configurations can be adopted. Provision of Set backs in step back building can gives optimized building configuration. Step back buildings can also be incorporated with the lateral load resisting members as different bracing systems or shear walls at different locations. And dynamic analysis by response spectrum method can be carried out according to IS 1893-2002 (Part 1) to know the performance of those building during earthquake.

2. ANALYSIS METHOD

Dynamic analysis by response spectrum method is performed on three dimensional model according to IS 1893-2002 (Part 1) on RCC structure, by assuming concrete as homogeneous, isotropic and elastic material with modulus of elasticity as 21.718 KN/mm^2 and Poisson's ratio as 0.17. Three dimensional models of step back buildings are generated with fixed support at foundation and analyzed for dynamic analysis in structural software STAAD Pro.

2.1 Geometrical parameters:

All building configurations are resting on ground of slope 15° and three different storey buildings as 10 storey, 8 storey and 6 storey with same plan has considered to perform analysis. Dimension of building in X and Z direction is symmetrical and unsymmetrical in Y direction with 6 bays of 5 m length each in both directions and storey height as 3 m. Each building is analyzed for 6 different configurations categorized as Case I: Step back building, Case II: Step back & set back building, Case III: Step back building with X bracing, Case IV: Step back building with V bracing, Case V: Step back building with chevron bracing, Case VI: Step back building with diagonal bracing. All six cases for 6 storey building is shown in Fig 2. Geometrical properties of structural elements are same for all configurations as size beam = $230 \times 700 \text{ mm}$, size of column = $700 \times 700 \text{ mm}$ and size of steel bracing used = ISMC300. Slab thickness for all floors is considered as 150 mm and wall thickness as 230 mm for exterior walls and 115 mm for interior walls.

Fig. 2. Building Configuration for 6 Storey

2.2 Load cases and seismic parameters:

The dead load and live load are taken as per IS 875 (Part 1 and 2) : 1987, dead load and floor finish load is calculated as member load and floor load respectively corresponding to the material density and size of member and thickness of floor. For residential building live load is assumed as 4 kN/m^2 . To perform dynamic analysis seismic parameters

are considered as per IS 1893 (Part 1) : 2002. All configurations of step back buildings are assumed in zone IV with zone factor Z as 0.24. Building frame is assumed as Special Moment Resisting Frame, hence response reduction factor is 5 and Importance factor for important building is 1.5. Response spectrum analysis is performed for soil type as hard soil and damping ratio as 0.05 with spectral acceleration as 0.036.

3. RESULTS AND DISCUSSION

This study incorporate the performance of buildings resting on slope in hilly region having different storey building with same plan and same size of structural members and steel bracings to identify the deviation in performance. Step back buildings are provided with 4 different types of bracing having same location on exterior face of building. Performed analysis gives the results in terms of storey drift, base shear and fundamental time period presented in graphical form. Results represents as comparative analysis of each parameter in same storey building with 6 different configurations as Step back building, Step back and set back building, Step back building with X bracing, Step back building with V bracing, Step back building with Diagonal bracing, Step back building with Chevron bracing.

3.1 Storey Drift:

Performed analysis shows significant variation in storey drift of 6 different models of 3 different heights of buildings. Storey drifts for 10 Storey, 8 storey and 6 Storey with 6 different configuration are shown in Fig 3, 4 & 5.

10 storey building shows considerable change in storey drift for different configuration. It is 15.72 mm for step back building where as 8.36 mm in step back & set back building and 9.07 and 9.1 mm for step back building with Chevron bracing and with V bracing. 46.81% and 42.11% reduction in drift compare to step back 10 storey building and 37.30% and 35.87 % for step back building with X bracing and step back building with diagonal bracing.

Fig. 3. Storey Drift for 10 Storey building.

Fig. 4. Storey Drift for 8 Storey building

For 8 storey building, maximum storey drift is observed in step back building as 13.21 mm and minimum is observed in step back & set back building as 6.22 mm. 52.91% decrease in drift by provision of set backs in step back building, 39.36% in step back building with Chevron bracing and with V bracing, and 33.53% for step back building with X bracing compare to step back building

Fig. 5. Storey Drift for 6 Storey building

In case of 6 storey building, 10.93 mm and 5.40 mm drift is obtained in step back building and in step back & set back building shows considerable variation in displacement about 50.59% reduction in displacement and 38.7% for step back building with V and Chevron bracing, 32.29% for step back building with X bracing.

Results on storey drift shows significant reduction in drift by providing set back in step back building configuration. And among four bracing systems provided V bracing gives considerable reduction in storey drift.

3.2 Base Shear:

Base shear is maximum expected lateral force that will occur due to seismic ground motion at the base of structure.

It depends on soil type and weight of building at different floors. This study compares the base shear of all building configuration of step back building represented in Fig 6.

Fig. 6. Comparison of Base Shear

Results show variations in base shear according to building configuration and height of building. It shows maximum base shear for step back building in 10 storey, 8 storey and 6 storey building models and least in step back and set back building configuration. 21.43% base shear reduction is found in step back and set back building of 10 storey and 26.53% and 34.76% for 8 storey and 6 storey building of same configuration. 6 storey building shows maximum base shear in all configuration.

3.3 Fundamental Time period:

Fig 7: Comparison of Fundamental Time Period

The dynamic behavior of building is represented by fundamental time period. More flexible building and more mass of building shows more fundamental time period. Larger the flexibility more the displacement of building during the fundamental time period. Present study compares

the same parameter obtained during dynamic analysis on all building models and represented in Fig 7.

Results shows reduced fundamental time period in step back and set back building as 1.66 seconds about 24.51% reduction compare to step back building and 10.41% in step back building with X bracing, V bracing and chevron bracing in 10 storey. For 8 storey and 6 storey building gives 29.95% and 37.41% reduction in period of step back and set back building.

4. CONCLUSIONS

Building on hills with different configurations are been analyzed to know its behavior during earthquake in earthquake prone areas. For improving the performance, provision of bracing systems and set back in step back building has been made. Results discussed above conclude different aspects when buildings are to be constructed on slope with reference to the parameter as storey drift, base shear and fundamental time period. Following are the highlighted points of conclusions:

1. Storey drift can be minimized by providing Step back & set back building. Bracings in step back building also reduced storey drift compare to step back building.
2. Providing bracings increased base shear which attract more lateral forces towards building for which short column effect can be produced. Thus, for step back and set back building can reduce base shear and minimizes the possibility for failure.

3. Step back and set back building shows lowest fundamental time period among all models.
4. This study also shows the effect of height of building on its performance during earthquake. For lowest building height as 6 storey performs effectively in respective of all parameters studied.
5. To optimize the response of buildings on sloping ground, this study proposes to opt for small height building with set back in step back building to achieve minimum risk of failure. Furthermore in this system the columns are cut at different levels as the result the short column effect minimizes which further helps in optimization of cost of structure.

Indian Scenario: Study of High Speed Rail Corridor, 2017

Apeksha Adesh Mendhe, Rakesh Kumar, N. J. Mistry

Department of Civil Engineering,
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

Abstract: Indian high speed railway network 2020 vision, tracks and rolling stocks operates significantly faster than traditional rail traffic service system. Coverage proposed corridor projects details via available technologies, objectives, mechanisms and Present status has been discussed. Automated rail based system for traffic related to high-speed rail as business industries by Govt. of India involves Mini-Ratna public sector Rail Vikas Nigam limited (RVNL). Four working network consists, Delhi-Mumbai (Package-I), b) Mumbai-Chennai (Package-II), c) Delhi-Kolkata (Package-III) and d) DELHI-CHANDIGARH-AMRITSAR, to spread as future perspective in Special Purpose Vehicle. Benefits over conventional rail trend and special purpose rail running at 160-200 and 250 -300 kmph respectively emphasized w.r.t Indian Conditions in the present paper.

Keywords: Rail Corridors, 2020- HS-Rail, and Conventional rail, Bullet train

History:

In 1975 – 82

(Ref: https://en.wikipedia.org/wiki/InterCity_125),

InterCity 125 introduced by British Rail's named diesel-powered **High Speed Train (HST)** fleet. Other than Britishers, Countries like including Austria, Belgium,

China, France, Germany, Italy, Japan, Poland, Portugal, Russia, South Korea, Spain, Sweden, Taiwan, Turkey, UK, US and Uzbekistan also development of high-speed systems designed for passenger travel. Europe coverage to international borders also. China has 22, 000 kilometres (14, 000 miles) of Rail-HS as of end December 2016, accounting for two-thirds of the world's total.

TABLE 1: Available Technologies and Mechanism for Bullet Train & conventional time reduction

Name of High Speed Train	Train Between		Speed	Reduced Travel Time (Minutes /Hr)	Method	Mechanism	Source
Rejuvenation (Fuxing)	Beijing	Shanghai	350	5	China's Shanghai Maglev	Magnetic levitation	http://news.xinhuanet.com/english/2017-08/20/c_136541020.htm

High Speed Rail Route Present status: In India, Ministry of Railways, Government of India, in terms of Public Private partnership. Railway system designed for speeds above 250kmph, called high-speed –sections implemented hierarchically by Japan, Spain, France and Germany. Among 16 World wide nations have high-speed railway, long spread of China 27, 000km of such tracks where tracks dedicated for high-speed trains stretch over 1, 000 kms. Unwillingness to newer production, government focuses on minor modifications to already present Rail-Infras'. But there is huge variation widely accepted is 200 Km/h i.e. 120 miles/ h. Some dedicated tracks and rolling stocks integrated high-speed rail system operates significantly faster than traditional rail traffic service system. Internationally, Japan first introduced in 1964 well known as Bullet Train.

Built, High-speed tracks of Continuously welded rail-on incorporates are grade-separated built, operated on standard gauge with large turning radius design pattern.

1. OBJECTIVES OF HS-RAIL IN INDIA

Documentary Coverage proposed corridor projects details via feasible studies and techno-economic investigations. Designing and planning; freeze technical parameters for HS-Rail at available assets, rolling stocks and operational conditions. Research part, main objective is financial modeling, public- private exploration, coordination with stakeholders and funding agencies, governmental clearances approvals. After clearancereal-estate development would be a key element of viability of these high-cost projects along with projects development, project executions, construction, up gradation, manufacturing, operations and maintenance of HS-Rail system or rail corridors. Automated rail based system for traffic related to high speed rail as business approved by Govt. of India.

Status/Role of HSRC

Subsidiary of RVNL on 25-07-2012 distinguished according to High Speed Rail Corporation of India Limited. Project proposed and launching, Delegates involved in H-S-Rail Corporation of India Limited by Shri Mallikarjun Kharge, (Hon'ble Minister of Railways on 29th October, 2013); Shri Arunendra Kumar, (Chairman Railway Board), Shri Satish Agnihotri (Chairman HSRC). 11/10/2017, International Conference ShriPiyushGoyal(Railway Minister, 2017) Addressed into about reliability, facilities atlong time coverage turned short time reach to destination. **Present status being, this** Special Purpose Vehicle has been incorporated in 2012 as a subsidiary of Rail Vikas Nigam Limited, which is a Mini-Ratna public sector enterprise of Government of India. Simultaneously, Managing Director MrAchalKhare (NHSRCL) declared project should be completed by Dec 2023.

Vision 2020

High Speed Rail Projects in terms of Article 69(2)(g) of Memorandum and Articles of Association of RVNL. Indian Railways' VISION 2020 envisaged High Speed Corridors. It was inspired by HS- rail corridor's revitalizing power of Railways in Japan, Europe, China, Taiwan and USA. India lonely planet not organized into HS- rail corridors.

Recent agenda being organizing into two prolong approaches. First raise the speed of segregated passenger corridors on trunk routes using conventional technology to 160 to 200 kmph. Second approach would be to identify a number of intercity routes, depending on viability, and build state-of-the-art high-speed corridors for speeds up to 350 kmph through on PPP mode in partnerships with the State Governments.8 corridors plan is proposed out of which under PPP partnership with state government at least 4 corridors of 2000 kms under construction at various stages of completion till 2020. Determined in 2015-16, Hon'ble Minister for Railways had announced of pursuance HS-Rail between Mumbai-Ahmadabad as first route of Bullet train for period of 2015-19 allocated Budget wasRs.65000 crore. Aspect will focus more on diamond quadrilateral, High Speed Rail & Elevated corridors commissioned.Japan Railway Technical Service (JARTS) was established in 1965 to provide advisories for High Speed railway, and its technical expertise has been inherited by JIC (Japan international Consultants). JIC deals with design, construction direction, O& M activities in a range of transportation system including urban rail and high speed rail and facilities for new transportation systems. Bullet train run between Ahmedabad-mumbai route claim total costs of 18.6 billion dollars[1]

Packages of work High-speed network

Contract Awarded For The Consultancy Of Feasibility Study For Diamond Quadrilateral Network Of High Speed Rail Corridors

a) Delhi-Mumbai (Package-I)

Feasibility Study Contract awarded to a Consortium of M/s The Third Railway Survey and Design Institute Group Corporation (CHINA) and Lahmeyer International (India) Pvt. Ltd, India

b) Mumbai-Chennai (Package-II)

Feasibility Study Contract awarded to a Consortium of M/s SYSTRA (FRANCE) - RITES- Ernest &Young LLP.

c) Delhi-Kolkata (Package-III)

Feasibility Study Contract awarded to a Consortium of M/s INECO (SPAIN) - M/s TYPASA- M/s Intercontinental Consultants and Technocrats Private Limited. Expected cost of 1583 km Delhi - Kolkata corridor is around Rs

84000 crores and is capable of reducing the travel time to just over 5 hrs from existing 17 hrs taken by Rajdhani.

d) DELHI-CHANDIGARH-AMRITSAR:

Pre-Feasibility study of this High Speed Rail Corridor is in progress. The consultant M/s Systra of France in Sep has submitted interim Report-II, 2015."HSRC-Delhi-Chandigarh-Amritsar High Speed Rail Corridor-India" contains information on the scope of the project including project overview and location. The profile also details project ownership and funding, gives a full project description, as well as information on contracts, tendering and key project contacts.

The "HSRC-Delhi-Chandigarh-Amritsar High Speed Rail Corridor-India" is part of Timetric's database of 82, 000+ construction projects. Database includes a 10+ year archive of completed projects, full coverage of all global projects with a value greater than \$25 million and key contact details for project managers, owners, consultants, contractors and bidders.

2. INITIAL PURPOSE OF PROJECTS AND FOREIGN INDUSTRY INVOLVEMENT

Tender work

Pending Tender work allotted to JIC, sept, 2017. According to report, Length of route is 534 Km [3]. It is likely to cover 11 stations at the speed of 320 Kmph (BKC, Thane, Virar, Dahanu, Vapi, Valsad, Surat, Bharuch, Vadodra, Anand and Finally Ahmedabad). It takes time of travel as 2 hours against 7 hours journey. Cost and budgets approximately Rs. 97, 636 Crores. It overcomes the Coverage given by Shatabdi express from Mumbai-Ahmedabad route. Involvement of industries corridor wise follows,

- Delhi-Chennai:

In Phase-I, Delhi-Nagpur section Under Government-to-Government cooperation, corridor upraised. Reports and logs for planning of HS- Rail corridor taken and completed by China Railway SIYUAN Survey and Design Group Co. Ltd. Feasibility study yet not done by group. High Speed Rail Corporation of India Ltd is the counterpart agency.

-Chennai-Bengaluru-Mysore:

China Railway ERYUAN ENGINEERING GROUP, feasibility studies in progress of speed rising for this section corridor. China Railway Eryuan Engineering Group has submitted Interim Report in June 2015. High Speed Rail Corporation of India Ltd is the counterpart agency.

-Mumbai-Ahmedabad:

Feasibility study was over past year. And RAIL VIKAS NIGAM LIMITED/ HIGH SPEED RAIL CORPORATION OF INDIA has been assigned implementation of high-speed rail projects. Mumbai-Ahmedabad is the first corridor,

which has been undertaken for implementation of proposed test project.

-FEASIBILITY STUDY OF MUMBAI - AHMEDABAD HIGH SPEED CORRIDOR:

MOU signed between JICA and Railway Ministry in 2013 and Joint feasibility report for Mumbai Ahmedabad HS- Rail system. JICA has submitted its Final Report of Feasibility Study of this corridor to Ministry of Railways in July 2015. Board members of Railway ministry decided to associate High Speed Rail Corporation of India Ltd. (HSRC) in this study.

Benefits and employment

Regarding Timetric project 'An individual travelling 100 km from Mumbai to Ahmedabad or vice-versa on work can commute in just about 30 minutes'. Due to HS-Rail, Mr. ArunJaitley (Finance Minister) says bullet trains potential in regenerating the economy but unless implemented. Direct benefits can be ensured by choosing effective economic model. Narendra Modi (PM, India) termed it into 'Suvidha' (facility), 'Suraksha', (Security) and will bring 'Rozgar' (Employment) and 'Raftar' (Speed). In near future it brings benefits into rural and urban sectors inequalities in various aspects like, employment, literacy, and infra facilities like health and sanitation viz bullet train. Various Townships and smart cities give hike to industrial development [2]. Industrialization report utilizes a wide range of primary and secondary sources, which are analyzed and presented in a consistent and easily accessible format. Timetric strictly follows a standardized research methodology to ensure high levels of data quality and these characteristics guarantee a unique report. This report provides details on the HSRC-Delhi-Chandigarh-Amritsar High Speed Rail Corridor-India including: Project description, overview and location, Ownership structure, funding status and key funding news for the project.

Smart Grids Controlling Technical and Non- Technical Losses in Indian Energy Sector

A. G. Matani¹, S. K. Doifode²

¹Mechanical Engineering Government College of Engineering, Amravati, Maharashtra, India

²Chemistry Department, Government College of Engineering, Amravati Maharashtra, India

Abstract: Technical losses consist mainly of power supply dissipation because of faulty transmission and distribution lines, transformers and measurement systems. There are other losses incurred as a result of actions that are outside the control of the power supply system comprising electricity theft, non-payment by customers, and errors in accounting and recordkeeping. Power theft losses, also referred to as commercial losses, are difficult to estimate but run into huge amounts. India and Brazil rank high on the list. Countries such as the U.S. and the U.K. also experience these losses but they are not as significant. The Indian experience has also shown that electricity thieves come from across segments: domestic users, commercial and industrial establishments, rural areas and large cities. Most of the time, this theft happens through tapping of electricity from live wires, which also poses risks to people's lives. The use of smart meters thus becomes extremely relevant in developing countries such as India.

This paper highlights the latest developments in enhancing energy efficiency by utilizing smart grid technology towards cleaner environment and efficient energy generation and utilization

Keywords: Technological advancements, high-quality electric power service, better system reliability, high penetrations of distributed, renewable generation sources.

1. INTRODUCTION

Due to rapid technological developments, demand for quality and reliability, and the need for distributed renewable energy generation, developing countries have no choice other than integrating smart grid technologies in the upgrading and development of their power systems. The energy efficiency and the smart grid industries will see a rapid growth as the demand grows for reducing global greenhouse emissions, increasing amounts of renewable energy integration into the grid and rising prices of fossil fuels. With the successful and widespread development of smart grids, countries can expect high-quality electric power service, better system reliability, and quality of service. These maximize energy use and energy savings, and enable higher penetration and greater use of renewable energy sources to capture environmental benefits.

2. INDIA'S ELECTRICITY SECTOR FACES A NUMBER OF CHALLENGES

- Unremitting growth in demand for power, fuelled by the country's rapid economic growth and rising living standards
- Poor access to electricity in rural areas. Although the electricity grid reaches over 93% of urban inhabitants, just under a half of the rural population has no access to electricity

- Grid inefficiencies. Distribution line loss levels are the among highest in the world, averaging over 30%. The northwest of the country and rural areas are the worst affected.
- Theft of supply. Electricity theft is an issue in all areas of the country.
- Inefficient electricity usage, particularly in agriculture. Irrigation pumping is energy-intensive and accounts for a substantial proportion of all power consumption.
- Poor grid reliability. Outages are frequent, due to aging infrastructure, poor maintenance, and demand outstripping supply.

3. BENEFITS OF HAVING A SMART METER INSTALLED

An energy saving opportunity: Smart meters provide businesses with the chance to fully engage with, and take control of, their energy use. With improved insight into consumption patterns provided by online smart meter reporting, businesses can identify and pursue potential new saving opportunities.

The end of estimated energy bills: Smart meters will bring an end to estimated billing, this means that businesses will only pay for the energy they use. For business that uses energy in a consistent manner, the end of estimated billing

will enable them to forecast their energy spend. This increased functionality will also support time-of-use tariffs and allow businesses to access the benefits this can provide, leading to further cost savings on energy use.

Switching energy supplier will be easier than ever before: The introduction of smart metering has the potential to boost competition across the energy market. This will not only make it easier and faster to switch energy suppliers, but provide businesses with the best possible deals available. Currently it can be difficult for businesses to secure the data they need to switch energy supplier, making it difficult to compare and search the market for the best prices and the right contract.

Increased control of energy usage: Most businesses don't know how much energy they use with a third not understanding their energy bills. Smart meters are designed to give back control to businesses and consumers to rebalance the energy market. The greater visibility of energy usage will quickly help to identify patterns of usage, equipment that consumes a high amount of energy and view consumption levels across the business. When you combine usage data with real time consumption data businesses have

increased control over their energy usage and energy saving opportunities.

4. SMART GRIDS MITIGATING THE INEFFICIENCY IN POWER SYSTEMS

Smart grids help to mitigate the inefficiency in power systems by monitoring where energy is wasted, both from the viewpoint of technical and non-technical losses. Non-technical losses in developing countries can often be attributed to uncollected debt, tampered meters and inconsistencies in billing due to corrupt meter readers or illegal connections. Power theft often contributes significantly to overall system losses in developing countries, reducing the economic performance of utilities. They account for power losses between 15-25% in India, 15% in South Africa, 20% in Nicaragua; the main implications are financial losses for utilities, network instability and higher costs for honest customers. High-voltage distribution lines can help prevent illegal connections and improve power quality and reliability. A smart metering infrastructure can help reduce further theft. Additionally, meter-based tariffs incentivize an efficient use of electricity, which can result in considerable load reduction

5. DISTRIBUTED GENERATION POLICIES TO TAKE ADVANTAGE OF SMART GRIDS

Smart Capabilities	Smart Policies
Enable higher penetration levels of clean distributed generation	Provide incentives for clean distributed resources, adopt best practices for net metering, require advanced metering infrastructure to support net metering, 52 and enable excess power sales through RPS set-asides, state PURPA policies or feed-in tariffs
Accelerate deployment and allow interconnected distributed generators to operate during utility outages	Update interconnection standards and utility operations to reflect smart grid capabilities and provide incentives to distributed resources to provide new services for the utility system
Dynamically integrate distributed wind and solar resources	Improve utility planning for renewable resources and support mechanisms to reduce integration costs – for example, intra-hour scheduling
Optimize voltage and reactive power on distribution systems	Remove barriers to utility investments that improve distribution system efficiency – for example, through decoupling, where retail customer rates for recovering fixed utility costs are adjusted periodically to keep utility revenue at the allowed level
Increase demand response to allow loads to follow variable renewable energy resources	Offer customers dynamic pricing options and incentives for other types of demand response programs; provide customers with easy access to useful energy consumption data, evaluation tools and targeted advice foster innovation in the marketplace for controls that automate the customer's response; and incorporate demand response in integrated resource planning
Provide physical connection and communication with wholesale and retail markets	Provide access to new markets and revenue streams for customer owned distributed generation
Provide timely information on each distributed generator, including type and availability, allow	Better incorporate distributed generation into energy forecasting and RPS compliance

Smart Capabilities	Smart Policies
tracking for RPS compliance and reduce tracking costs	
Easier and timely interconnection distributed generation for exporting power to the grid	Provide transparent cost information and fair cost allocation for interconnection; streamline and update interconnection study requirements for exporting power to the grid

6. NOVEL SMART GRID PILOTS UNDER SMART GRID TASK FORCE IN INDIA

Cyan- the integrated system and software design company delivering mesh based flexible wireless solutions for utility metering and lighting control is presently providing Enzen Global Solutions Pvt. Ltd. (Enzen) for a large pilot project being implemented for Chamundeshwari Electricity Supply Corporation Limited (CESC), Mysore, Karnataka in southwest India. Enzen is awarded a contract to provide energy infrastructure solutions to CESC and Cyan will act as Enzen's end-to-end solution provider for the smart metering elements of the contract. Cyan will supply its 865MHz RF mesh communication network (including the modules, data concentrator units and head end software), a Meter Data Acquisition System and 21, 824 smart meters. Cyan will manage the supply chain through local meter manufacturer partners. In addition, Cyan will provide facility management services to CESC in Mysore for a period of two years post deployment, which is expected to represent around 10% of the order value.

The project is the first of 14 smart grid pilots under the Smart Grid Task Force in India being funded by India's Ministry of Power to be rolled out. This is the first commercial implementation of AMI technology by a public utility for consumers in India.

7. CONCLUSIONS

In India, though power theft is one of the strongest incentives to install smart meters, there are other compelling factors such as the need to reduce technical power losses and peak power deficit and bringing in more efficient transmission of electricity to rewarding consumers who help in reducing peak power demand. Currently, governments in Puducherry, Maharashtra, Andhra Pradesh, Karnataka and New Delhi have initiated the process of installing smart meters. Smart grid technologies will help utilities in India optimize efficient energy use in distribution networks, Smart grid technologies can enable utilities to employ demand response mechanism, curtailing power at the time of shortages and helping avoid blackouts. Additionally, integration of renewable energy like rooftop solar PVs into the grid will add to generation capacity.

Role of Industrial Engineers in the Growth of Indian Foundry Industry

Gajanan Patange

Department of Mechanical Engineering, Chandubhai S Patel Institute of Technology,
Charotar University of Science and Technology (CHARUSAT), Changa, , Gujarat, India

Abstract: This study examines various role of Industrial Engineers in the Growth of Indian foundry industry. In this study, an importance of industrial engineering was identified pertaining to prosperity of Indian foundry. This study has attempted to identify need based areas with respect to their importance for effective use. The findings of this study may be used for developing curriculum activities in Industrial engineering field for benefit of Indian foundry.

Keywords: Indian foundry, Industrial engineering field, role Industrial Engineers.

1. INTRODUCTION

Indian Foundry Industry enjoying a status of the second largest producer of cast components in the world with about 10 million tons production per annum (Indian foundry congress, 2017).

India's foundry industry, which is the third biggest globally in terms of production capacity (10 million tonnes in FY16) after China (40 million tonnes) and the US (11 million tonnes), has an installed capacity of 15 million tonnes per year.

Foundry Industry has a turnover of approx. USD 19 billion with exports approx. USD 2.5 billion. However, Grey iron castings have the major share i.e. approx 68% of total castings produced. The Indian foundry industry manufacturers metal cast components for applications in Auto, Tractor, Railways, Machine tools, Sanitary, Pipe Fittings, Defence, Aerospace, Earth Moving, Textile, Cement, Electrical, Power machinery, Pumps / Valves, Wind turbine generators etc.

Steel 380 magazine(May 2017) India (<http://news.steel-360.com/steel/growing-demand-foundry-sector/>)

Market research analysts have predicted that the foundry market in India will grow steadily in coming year over 10% by 2020. This market research analysis identifies the role of Industrial Engineers in the Growth of Indian Foundry Industry (Technavio reports, 2017)

In this paper, various roles of Industrial Engineers have been chosen on the basis of literature review. This paper is organized as the main sections namely areas, Discussions, Conclusions and future scope.

2. AREAS WHERE INDUSTRIAL ENGINEERING APPROACHES CAN BE USED

2.1 Marketing

In early days marketing work might be suitable for non technical paper but now a day's techno-commercial knowledge is very much essential in highly competitive work. In foundry this techno-economic knowledge reduce the burden during process improvement . Marketing Research means developing research questions, collecting data, analyzing it and drawing inferences, with a view to making better business decisions. Marketing must target and communicate with engineers and technical buyers. (Pahl, G., & Beitz, W., 2013; Scheer, A. W., 2012). Indian foundry has huge demand in automobile industry within India also(Foundry Informatics centre, 2017)

2.2 Casting Development

APQP (Advanced Product Quality Planning) is a scientific method of defining and establishing the steps necessary to ensure that a product satisfies the customer. Effective product quality planning depends on a company's top management's commitment to the effort required in meeting customer specifications.

Design failure mode and effects analysis

Design for manufacturing and assembly

APQP is an emerging field among researchers. Some studies have reported the successful use of the APQP for quality improvement in existing products. APQP have evolved to with product development and process improvement. The growth of APQP focus on quality methods. It provide a inclusive and flexible system for maximizing business profit and has been considered

revolutionary system (Kalpakjian, S., & Schmid, S. R., 2014; Mittal, K., Kaushik, P., & Khanduja, D., 2012).

The series of resins obtained, now a days. These resins (binders) and acids (catalysts) make a two part no bake self-set system (popularly known as FNB in foundry terms) With growth of Foundry industry, several self-sets have been introduced periodically for making molds and cores. Other primitive binders like cement, molasses and many proprietary binders have largely been replaced by modern organic binders, which meet requirements of higher productivity, better out of box and handling strength of molds and cores, rapid production cycle, better de-coring property and eventually better casting finish. Furan sand is very useful in all above conditions (Ghosh, D., 2013).

Foundries which use CAD/CAM as well as simulation tools reported 30% faster casting development also 50% lower rejection rate, compared to foundries which do not employ these technologies. Few years back, the main concern for both CAD/CAM and simulation technology was cost, whereas today the concerns have changed to technical support as well as trained manpower availability. The survey focus many such insights useful for technology strategy planning at all foundry level (Joshi, D., & Ravi, B., 2010).

Manufacturing simulation is a digital engineering tool and procedures have had a positive impact on the manufacturing industry. The increased competition in the global marketplace is forcing industrial manufacturers to develop their production systems by increasing flexibility, improving quality and lowering production costs. With the aid of simulation techniques, the understanding of manufacturing systems may be enhanced and alternative solutions may be tested. Simulation has, thus, played an active role in industrial development in early years (Petter Solding, Damir Petku & Nawzad Mardan, 2009; V.S. Saravanan (2017)

2.3 Environmental Engineering

Regarding industrial pollution, environmental acts have been getting very stringent in various countries and efficient use of resources is having great importance. Industries are always under pressure to improve environmental performance of manufacturing activities based on waste management principle, From 2004, the pollution prevention activities in the western countries resulted in a reduction of 25% in waste generation while 34% increase in industrial production (Grasso, D., & Burkins, M. 2010; Fore, S., and C. T. Mbohwa, 2010).

From 1980s onwards, most of foundry industries, marked as environmentally destructive, In the view of Cleaner production, thus productive goals levelled with environmental issues now become essential, which focus the necessity for the development of environmental

performance indicators that are able to expose impacts of industrial operation on the environment the definition of indicators for environmental performance analysis (EPA) must consider the specifications of produced goods and the nature of adopted processes. (Rebelato, M. G., et al, 2017). Over the last 10 years, stringent regulations put the manufacturing industry to take serious actions towards greener production through implementation of best available techniques (BATs), industrial waste still need guidance to minimize environmental impacts of manufacturing processes. The foundry industry remains one of the most i waste generating fieldr and therefore, iron casting and used a life- cycle approach (LCA) to evaluate the performance and cross-media effects of the BATs applicable for this industry(Yilmaz, O., Anctil, A., & Karanfil, T., 2015).)

With very limited resources and their disposal, foundry small and medium-sized firms always find themselves unable to cope up with the changes necessary to meet environmental regulations and product controls. Small-scale operations such as metalworking, casting, machine tools etc. are frequently among the worst offenders of environmental regulations across world. Energy saving systems may be well suited to the requirements of SMEs for pollution control or waste disposal.(Wadhwa R.S. 2014)

Sustainable manufacturing seems to be a rapidly developing areas and it would be expected that there is a growing body of knowledge in this field (Despeisse, M., Mbaye, F., Ball, P. D., & Levers, A. 2012).

Environmental factors may play a major role in selecting an optimal process planning scheme. (Shojaeipour, S., 2015)..

2.4 Energy Management

Foundry is an energy intensive industry. Energy costs for foundries are about 15% of the cost of castings. In early years foundries have become energy aware and most of medium scale have installed on-line energy monitoring systems for report energy consumption (kWh) per tonne(Schulze, M., Nehler, H., Ottosson, M., & Thollander, P., 2016).

Energy efficiency is recognized as a primary measures to increase the competitiveness of the indus- trial sector, and in particular for small and medium-sized enterprises (SMEs), in which energy efficiency measures. Hence, it is very crucial to have a precise as well as punctual knowledge of the barriers to be handled in the decision-making process of adopting an energy management process (Cagno, E., Ramirez-Portilla, A., et al, 2015; Noro, M., & Lazzarin, R. M., 2016; May, G., Stahl, B., et al, 2016)

Although the energy saving in a foundry is a very difficult task, realizing heat recovery, may give rise to an energy saving up to 20%. Regarding the production process in cast

iron. Further savings may be possible after careful analysis ((Sa, A., Thollander, P., & Cagno, E., 2015; Lazzarin, R. M., & Noro, M., 2015; Arjunwadkar, S. et al).

2.5 Safety Engineering

A workers working in very hot environment is at more risk of heat-related disorders and safety problems. Thus safety needs to evaluate the risk and warning rate of hot environment without compromising productivity of the organization.

Improvement of quality of casting and manufacturing processes is a difficult task, but it is beneficial for the foundry. In order to manufacture casts properly in terms of quality, at the lowest own costs possible, it is essential to improve the manufacturing systems at all stages of manufacturing processes, through elimination of waste, as well as inconvenient and dangerous activities. Good organization is employee-friendly and it promotes occupational health and safety. Various safety measures are to be implemented in coming year (.Ilangkumaran, M et al., 2015; Kukla, S., 2016; Sen, S., 2014)

The reliability analysis of the casting process is useful in foundry work using a probabilistic approach. Foundry in many developing countries suffering from poor quality due to improper management, lack of resources and very wrong working practices, which results in the decrement of productivity(Kumar, A., Varshney, A., & Ram, M. 2015).

2.6 Maintenance Engineering

The foundry industry focus has changed from a labour-intensive to a technology-intensive industry. However, technology cannot be effective without excellent maintenance management (Saniuk, A et al, 2015; Kumar, A., Varshney, A., & Ram, M., 2015)..

2.7 Quality Management and system Engineer

Lean manufacturing is often seen as a set of tools that reduce the total cost and improve the quality of manufactured products. The lean management philosophy is one which targets waste reduction in every facet of the manufacturing business; however, only recently have studies linked lean management philosophies with improving environmental sustainability. The foundry industry, has significant challenges in the current regulatory and political climate with developing an economically and environmentally sustainable business model. Lean manufacturing always proven as a model for both economic sustainability as well as environmental stewardship. Several recent studies have shown that both lean and green techniques and “zero-waste” policies also lead to reductions in overall cost. While these strategies have been examined for general manufacturing, they have not been investigated in detail for the foundry industry.

Presently lean and green manufacturing are the two most important strategies for improving operations and achieving service excellence in manufacturing industries. Lean manufacturing is being extensively practiced and implemented by different industries in many countries throughout the world for improving productivity (Desai DA, 2012.. Singh, T., & Dubey, R., 2013 Suresh Prasad Dinesh Khanduja, 2016)

2.8 Value Engineering

Product life cycle is challenge facing manufacturers presently as efforts to increase efficiency throughout the life cycle do not only lead to an extended responsibility of the concerned parties. As a result, economically successful business areas can be explored. Whether new service concepts are required, new regulations have been passed or consumers values are changing, the differences between business areas are disappearing. “Life Cycle Management” (LCM) considers the product life cycle as a whole and optimizes the interaction of product design, manufacturing and life cycle activities. The goal of this approach is to protect resources and maximize the effectiveness during usage by means of Life Cycle Assessment, Product Data Management, Technical Support and last but not least by Life Cycle Costing. This paper shows the existing approaches of LCM and discusses their visions and further development (Salonitis, K et al., 2016)

Foundry technologies realized with aid of the processes allocation provides an opportunity to arrange a holistic picture of its resource efficiency and the expenses at the various stages of its life cycle. The review of the processes and activities for the whole chain of creating an added value allows defining the most expensive stages and, therefore, creating the opportunities for applying the resource-saving technologies (Vidayev et al., 2014; Nallusamy, S, 2016). Expert systems in technology can be used now a days to increase the productivity in a comprehensive ways (Macioł, A., Wrona, R., & Stawowy, A, 2016; Zimwara, D., 2013)..)

2.9 Activity Based Cost saving

Product life cycle is challenge facing manufacturers presently as efforts to increase efficiency throughout the life. “Life Cycle Management” (LCM) may be the product life cycle as a whole and optimizes the interaction of product design, manufacturing and life cycle activities. The goal of this approach is to protect resources and maximize the effectiveness during usage by means of Life Cycle Assessment, Product Data Management, Technical Support and last but not least by Life Cycle Costing.

Activity-Based Costing (ABC) is a cost accounting method that can overcome many of the limitations of Traditional Cost Accounting (TCA) methods. Cost for each department in the foundry are estimated by regular engineering procedures. But cost- estimating relationship model that

mathematically describes the cost of final castings as a function of all consumable resources is constructed. A Work-In-Process (WIP) flow through the different production centres is analyzed and costs of available resources are allocated for all foundry centres, cost rates are derived, accordingly the ABC method for estimating production cost is discussed and presented. Comparison between the results of ABC method and the results of TCA method has been carried out. Finally results are discussed, recommendations are presented, and avenues for related future works are proposed (Al-Tahat, M. D., & Abbas, A. R. 2012).

3. DISCUSSIONS, CONCLUSIONS AND FUTURE SCOPE

This study has attempted to identify the most important role. Based on the literature review. We may focus on right balance between technological up gradation and internal operational excellence through various tools and techniques like Total Productive Maintenance (TPM), Value Stream mapping (VSM), Maynard Operation Sequence Technique (MOST) any many more to improve our efficiency and efficacy as well in terms of Production, Quality, Cost, Delivery, Safety, Morale and Environment. Specific initiatives like lean approach with frugal mind set in utilizing all our resources at optimal level and focus towards elimination of waste in our process drives us towards becoming cost competitive

These roles may help managers of industry to resolve the critical issues. Industrial engineers possess a bachelor's degree, but very few typically in industrial engineering. However, many industrial engineers have post graduate degrees after mechanical engineering, electrical engineering, manufacturing engineering, industrial engineering technology, or general engineering. Above discussed points are suitable for industrial engineering field.

In the future research to determine weights of the each field a sub branch of Industrial engineering may be possible as per need.

In this study there were only 9 fields are taken in consideration, but more fields can be included and resolve in future.

A Study of Factors Affecting Entrepreneurship in Industries at Madhya Pradesh

Nishith Dubey, C. M. Sadiwala

RKDF University, Bhopal, Madhya Pradesh, India

Abstract: Individuals innovate and to create new businesses. Many support mechanisms act as a facilitators and promoter of entrepreneurship. Risk taking, innovation, creativity and learning from past are some of the few important characteristics of an individual who aspires to become a successful entrepreneur. to result into change within the organization. Entrepreneurship is a level field and all have equal opportunities to perform, it is one who exploits himself completely for the cause becomes successful. In This study, various factors affecting entrepreneurship in the state of Madhya Pradesh was researched. The sample of 80 entrepreneurs and would be entrepreneurs was drawn on random basis in the state of Madhya Pradesh.

Keyword: entrepreneurship, Madhya Pradesh

1. INTRODUCTION

The significance of entrepreneurship and innovation as a mechanism for growth has been a widely accepted concept (Peters and Waterman, 1982; Kanter, 1983; Drucker, 1985; Pinchot, 1985; Slevin and Covin, 1990). Covin and Slevin (1991) suggested that entrepreneurship is studied for many reasons but the over-riding reason for the current interest is the widespread belief that entrepreneurial activity stimulates general economic development as well as economic performance of individual firms. From macro social (promotion of economic growth in the developed and developing countries) and organisational level (improvement of organisational performance) considerations, a further study of various modes of management may have high social relevance. Schollhammer (1982) stated that entrepreneurship is the key element for gaining competitive advantage and consequently greater financial rewards. In a competitive environment, entrepreneurship is an essential element in the long range success of every business organisation, small or large, new or long-established. Firms adopt entrepreneurship in the hope and under the assumption that the associated behaviours will help to create or sustain a high level of performance (Cornwall and Perlman, 1990).

2. ENTREPRENEURSHIP PHENOMENON

Trends identified in business state that dynamic corporations of the future should simultaneously be trying alternative ways of doing things in competition within themselves. Many organizations today do not pay employees for attendance, but pay the competing groups for modules of work done. These groups may be in the form of pools contracted for a certain amount of work over a certain time period for a lump sum. The members of the pool would be responsible for apportioning work, fixing pay,

setting work hours or even whether to subcontract part of the work.

Entrepreneur seems to be one of the most important elements for entrepreneurial success. The importance of entrepreneurial role has been emphasized by many researchers. Gobeli and Rudelius (1985), Pinchot (1985), and Sexton and Bowman (1985) discovered that the various roles performed by an entrepreneur vary in importance according to the stage of the innovation process.

He is an inventor, decision-maker, sponsor and programme manager. This suggests that different individuals with different characteristics may be required by a company at different times, and for different types of work. The type of organisation, its life-cycle stage, its size, and its rate of growth all therefore have a bearing on the source and types of individuals it will appoint to its key roles. Kirton (1984) proposed Kirton Adaption-Innovation Inventory. Adaptors produce a sufficiency of ideas, but these are based on an existing definition of a problem, in other words doing something "better". Adaptors accept the paradigms and familiar assumptions underlying an organisation, hence their solution is more palatable to the establishment which shares those assumptions. Innovators, in contrast, do things differently.

Their proposals are less expected, and thus less acceptable. Innovators are likely to be treated with suspicion. They are seen as abrasive and insensitive, who appear unaware of the havoc they cause. Kirton suggests that organisations in general, and especially large ones, tend to be adaptive in order to minimise risk. Over time, organisations develop, through recruitment, a cognitive style mean. In order to implement changes, individuals have to be different from the organisation's current mean - thus adaptors will act as

change agents in innovative environments, and innovators in stable environments.

The team may be comprised of many employees within the corporation. Within the corporate setting, there are more people and roles involved in the entrepreneurial process (Gobeli and Rudelius, 1985) than in the conventional linking of entrepreneurship with the founding and development of a firm, sponsors i.e., senior managers who support the progress of the innovation, godfathers i.e., top-level managers who give their blessings to the process, and inventors i.e., the originators of the idea, as well as the champions who develop and push for the implementation of an innovation, all have a legitimate claim to the title of corporate entrepreneur. The entrepreneur should possess personality traits so as to harness potential of all concerned in the project. Howell and Higgins (1990) described an entrepreneur as a champion. Entrepreneur must be a good opportunity identifier.

3. ENTREPRENEURSHIP IN MADHYA PRADESH

State of Madhya Pradesh is rich in natural resources and also has been hub of activities as it the central part of the country. Due to its strategic location, resources it has tremendous potential of entrepreneurship. As compared to states like Gujarat Maharashtra, Punjab state of Madhya Pradesh is low in entrepreneurship but this also provides an opportunity for would be entrepreneurs. There are traditional industries which are conventional, low technology and labour/semi-automated which are evolutionary in nature with very slow phenomenon of development and change. Many of these are process industries where the sub-processes are interrelated and not independent. Also there are hi-tech industries. These industries are mechanized/ automated/knowledge-based and use latest upgraded technology. In these types of industries, adoption of advanced technology is very fast. They have extended knowledge base and are revolutionary in nature.

4. OBJECTIVE OF THE STUDY

To determine the factors affecting Entrepreneurship in Industries at Madhya Pradesh.

5. RESEARCH METHODOLOGY

The present investigation is an exploratory study to determine the factors affecting Entrepreneurship in Industries at Madhya Pradesh.

6. THE DESIGN & SAMPLE

The sample of 80 entrepreneurs and would be entrepreneurs was drawn on random basis in the state of Madhya Pradesh while controlling the effect of extraneous variables such as gender, background, education, and hierarchy by randomization and elimination. The incomplete sets of

measures were rejected besides those in which socially desirability scores were found beyond optimum range.

7. TOOLS FOR DATA COLLECTION

Primary data was collected as per requirement of the research design. For this, one standardized psychometric measures were developed to elicit the responses from entrepreneurs and would be entrepreneurs.

8. RESULTS

Factor analysis resulted into following factors which affect entrepreneurship in the state of Madhya Pradesh..

1. Technology transfer
2. New product development
3. Ancillary promotion
4. Marketing Channels
5. Quality support system
6. Training and Development
7. Entrepreneurship promotion policies
8. Infrastructure availability
9. Financial schemes
10. Trained Labour
11. Power
12. Export promotion
13. Alternate resources.

9. CONCLUSION

Factors affecting entrepreneurship in the state of Madhya Pradesh are Technology transfer, New product development, Ancillary promotion, Marketing Channels, Quality support system, Training and Development, Entrepreneurship promotion policies, Infrastructure availability, Financial schemes, Trained Labour, Power, Export promotion, Alternate power resources. For flourishing entrepreneurship in the state of Madhya Pradesh formal measures need to be taken to promote these factors. Policy makers can use these factors to make conducive policies, agencies engaged in the promotion of entrepreneurship may priorities their preferences as per these factors. Training and development institutions in the field of entrepreneurship should increase their efforts and agencies in the field of quality control should make easy access for entrepreneurs.

Optimization of Man Power in Warehouse by Using Lepaksnel Model

Rathin Unadkat¹, B.N. Bhagat², R.S. Singh³

^{1,2}Productivity Services Department (RM), Tata Steel Limited, Jamshedpur, Jharkhand, India

³Productivity Services Department, Tata Steel Limited, Jamshedpur, Jharkhand, India

Abstract: It has become increasingly difficult for business to keep a competitive edge in the global market. The increase in price of the products directly affects the profits of the business. It has become imperative for the organizations to cut the operating cost while remaining more efficient and effective in terms of product and its quality. In the wake of becoming more cost efficient, more and more firms are opting for outsourcing of functions which are not considered as their area of expertise. Strategic outsourcing is considered as an important tool for implementing rapid strategic changes.

The case study tries to reengineer the process of material issuance from warehouse and the use of strategic outsourcing in warehouse. The business has initiated a project to reduce the floating inventory of stores at individual department by planning to run the store two shifts per day and start door to door delivery of materials from the store to respective departments.

Keywords: Strategic outsourcing, Warehouse, BPR, Rationalization

1. INTRODUCTION

The mining area is currently going through the expansion phase, so it has been imperative for them to work more efficiently and effectively. Looking at the material requirement of the department and to reduce the floating inventory it was decided to operate stores department in 2 shifts (General & 2nd Shift). With the increase in shift operation the need for the increase in manpower will be dealt by strategically outsourcing of activities with low strategic value.

2. ANALYSIS OF EXISTING SYSTEM

In the existing system of store there are mainly three sections for Material receiving & verification.

Fig. 1. Major sections in Central Stores

2.1 Material & Process flow Mapping

Fig. 2. Existing material flow

The existing material flow starts from indenting of material to receiving of material at each of the sections dedicated for the type of material. For the current functioning of stores the manpower deployment in various sections of store is shown in table below. The persons deployed are for receiving, storage & issuing of goods. Each department sends its own resources to bring material from central stores.

The process of issuing of material is shown in flow diagram mentioned below. The process starts from indenting of material by raising material requisition and ends at material receipt at the department.

Fig. 3. Current Material issue process

3. NEW REQUIREMENT FOR STORES

Division has taken inventory management project to reduce the floating inventory in individual department at Division and planning to run stores in 2 shift operations (General + B shift) for Material Issue from central store to individual departments. B shift operation will run only for spares delivery of Beneficiation plant. Cement, Steels and all other heavy material will be issued in General shift. Out of total inventory 70-75% of inventory is belong to beneficiation group. Door to door delivery of goods to individual departments.

As a part of evaluating requirement the process of material issuance was reevaluated and redesigned.

Fig. 4. Proposed Material issue process

With the new process there will be elimination of two steps “send the crew to store” & “gate entry” and addition of a step of “send material to department”

4. STRATEGIC OUTSOURCING & MANPOWER PLANNING

Many employers carefully select a core group of employees, invest in them, and take elaborate measures to reduce their turnover and maintain their attachment to the firm. For this they outsource certain type of jobs to service providers. This is done by using Lepak & Snell model shown below.

Fig. 5. Operating Philosophy (Lepak & Snell's Model)

On the basis of this model the jobs with high strategic value and high uniqueness of human capital should be retained and one with low strategic value and low uniqueness of human capital can be outsourced. Other than the two mentioned category can be outsourced based on discussion and their role and requirement to the company.

For the current deployment of Manpower for b shift operation it will require provision of additional store keeper and mazdoor for running store in B Shift. A total of four people will be required. For door delivery system presently each department sends its own resources for bringing material from central stores. With the proposed system a central door delivery team will supply material from Central stores to individual departments. Door delivery operation will run only in General-shift and it will be managed by service providers, however to coordinate the activities of door delivery team one person on company roll will be required.

Shifting of material within the premises of central store is of low strategic value and low human capital it can be managed by deploying resources through service providers resulting into rationalization of one person on company role. Implementation of Door Delivery system will lead to rationalization total of six mazdoor and drivers engaged by individual departments for bringing material from central store. Rationalization three Supply Associates PR and other related activities will be done by Officers provided with the departments. Merger of sub-stores of beneficiation plant & engineering services to have a common department store each. This will result rationalization of three stores assistant.

Final deployment of persons after 2 shift working & door delivery of goods to the department is shown in table below.

5. CONCLUSION

Designation	Existing	Proposed	Change Wrt Existing	Remarks
Level 1	3	5	2	
Level 2	7	7	0	
Level 3	7	8	1	
Level 4	1	1	0	
Level 5	8	8	0	Note- Home delivery will be managed by service providers
Level 6	12	0	-12	They are deployed for help in material unloading/handling, tying sling on cranes during

Designation	Existing	Proposed	Change Wrt Existing	Remarks
				material receiving at the central stores. Material receiving and Verification(Receipt section)
Level 7	1	0	-1	Driver to be managed by service provider
Total Stores	39	29	-10	

With the help of lepaksnel model there will be rationalization of 13 people as those jobs are low end jobs which have low skill level requirement and low criticality.

Measuring Emotional Labour of the Employees in the Hotel Industry

Rashmi Garg, Renuka Garg

Department of Business and Industrial Management
Veer Narmad South Gujarat University, Surat, Gujarat, India

Abstract: The study was undertaken with the objective to identify the dimensions that will help to measure emotional labor of the employees in the hotel industry. Descriptive research design was adopted for the study. The sample unit was hotel employees. Non probability convenience sampling procedure was adopted and 280 hotel employees were personally contacted to measure the emotional labor experienced by the employees. Data were collected through structured questionnaire. Factor analysis was conducted for data reduction and dimension identification. Employees do more of surface acting when interacting with hotel guests. Situations should be created where employees should exhibit less of surface acting. Management need to internalize the hotel process so that employees exhibit deep acting when delivering services to the customers. Employees in the hotel industry experience emotional labor because of customer orientation. Self awareness is an important variable which affects emotional labor.

Keywords: Emotional Intelligence, Emotional Labor Acting Strategies, Customer Orientation, Recognition (Self Awareness), Surface Acting, Emotional Dissonance, Job Strain, Hotel Industry

1. INTRODUCTION

Due to increased competitions in the hospitality industry, organizations place much emphasis on “service with a smile” to maximize service quality and customer satisfaction. Managing service employees’ emotional display has been recognized as an important aspect of maintaining loyal customers. Frontline employees directly interact with customers and are also referred as boundary spanners. They are the connecting link between the external customer, an environment and the internal operations of the organization. They serve a critical function in understanding, filtering and interpreting information to and from the organization and its external constituencies. Their skills and experience covers the wide range of jobs and careers. In industries such as the fast food, hotels, telecommunications and retailing, the boundary spanners are the least skilled, lowest paid employees. They are the order takers, front desk employees, telephone operators, store clerks, truck drivers and the delivery people. But in the other industries, they are well paid, highly educated professionals- such as doctors, lawyers, accountants, consultants, architects and the teachers. Boundary spanning positions are often high stress jobs. A part from the mental and physical skills, these positions require extraordinary levels of emotional labor, they often demand an ability to handle interpersonal and organizational conflict and call on employee to make real time trade-offs between quality and productivity on the job. These stresses and trade-offs results in service delivery failure creates a bad impression on the customers. Service organization demands from their employees to show some positive emotions to their

customers and to hide their negative emotions such as anger and frustration. This concept of following the expressional norms of organization by the employees is termed as emotional labor. “It is what employees perform when they are required to feel or at least project the appearance of certain emotions as they engage in job relevant interactions (Hochschild, 1983)”. The objective of the study is to identify the dimensions related to emotional labor experienced by the employees in the hotel industry.

2. LITERATURE REVIEW

The hidden role of emotions in performing the duties effectively at workplace was first put forth by American sociologist, Arlie Hochschild, in 1983 in her book, “The Managed Heart: The Commercialization of Human Feelings”. Her work drew inspiration from the dramaturgical perspective put forth by Erving Goffman. The dramaturgical perspective urged that the work place is the stage where employee is the actor and the customer is the audience. The labor which was performed in terms of emotion was thus called an emotional labor. According to Hochschild, emotional labor is the labor that which goes beyond the physical and mental skills needed to deliver quality service. It means delivering smiles, making eye contact, showing sincere interest and engaging in friendly conversation with the people who are essentially strangers and who may or may not be ever seen again. Friendliness, courtesy, empathy directed toward customers require great amount of emotional labor from the frontline employees. It often requires employees to suppress their true feelings to be effective in their jobs. A frontline employee who is

having a bad day or isn't feeling just right is still expected to put on the face of the organization when dealing with the customers'. She defined emotional labor as "The management of feeling to create facial and bodily display with a focus on showing appropriate organizationally desired emotions". For emotional labor to take place at the work place, three conditions should be fulfilled to:-First, they require employees to interact face-to-face or voice to-voice with other people, like clients, customers, and guests. Second, they require the worker to produce an emotional state in another person. Third, employee's emotional expressions are formed by organizational prescribed display rules and requirements.

Through Factor analysis 6 dimensions were identified to measure emotional labor of the employees which are presented below:-

2.1 Emotional Intelligence

It is the individual's capability to identify and understand emotional information and to generate and regulate emotions that promote emotional and intellectual growth (Salovey and Mayer, 1990). It is a set of individual's capabilities to understand, regulate, use, and manage their emotions (Law et al., 2004). Conceptualization and operationalization of Emotional intelligence can be viewed from the ability model and the mixed model (Van Rooy and Viswesvaran, 2004). It is characterized by considerable face-to-face and voice to voice interaction of frontline employees with customers, so the frontline employees are required to manage, regulate, and control their emotions effectively (Karatepe, 2011).

2.2 Emotional Labor Acting Strategies

Emotional Labor employees usually use two distinctive acting strategies to satisfy organizational requirements for emotional expression (Hochschild, 1983):-

Surface acting (Faking the expected emotions) -It refers to the management of external emotional expression without any changes in inner feelings. Grandey (2003) states that surface Acting corresponds to response-focused emotional

regulation in which employees modify the outward expression of their emotions through faking emotional displays.

Deep acting (Actually experiencing the desired emotions)-

It requires the modification of an employee's inner feelings to express organizationally desired emotion. It resembles an antecedent-focused emotional regulation strategy (Groth et al., 2009), in which individuals attempt to modify how they perceive or interpret a situation to adjust their emotional response (Lam and Chen, 2012).

2.3 Customer Orientation-It has been studied at the organizational and individual worker levels .At the organizational level, it is an integral component of a market orientation (Deshpande et al., 1993; Narver and Slater, 1990). At the individual level it describes a personal resource of an employee and is defined as "an employee's tendency or predisposition to meet customer needs in an on-the-job context" (Brown et al., 2002)

2.4 Recognition (Accurate Self Awareness)- According to Steve Langhorn (2004) general manager individual emotional competencies performance depends on his ability to understand and recognize his own emotions.

2.5 Surface Acting -It is one of the form of emotional expression strategy wherein employees fake their true emotions. It involves an attempt to change what is privately felt (Hochschild, 1983).

2.6 Emotional Dissonance/ Job Strain-It refers to the differences arising out of the emotions displayed and the emotions genuinely felt. According to Morris and Feldman (1996), when there is a mismatch between genuinely felt and organizationally required emotions then greater control, skill, and attentive action is required. It is a work stressor and occurs widely among employees in frontline service jobs of the hospitality industry (Karatepe and Aleshinloye, 2009; Van Dijk and Kirk, 2007).

3. RESEARCH METHODOLOGY

3.1 Problem statement

The present study is to measure the emotional labor of the employees in the hotel industry.

3.2 Objective of the study

To identify the dimension related to emotional labor experienced by the employees in the hotel industry.

3.3 Research plan: Research Approach, Design, Method

Research Design	Research Methods	Sampling Plan			Instrument
		Sample Unit	Sample Size	Sampling Procedure	
Descriptive	Survey	Frontline employees	280	Non-probability Convenience	Undisguised structured

3.5 Output of Factor Analysis

Component	Item	Score	Dimension
1	I always know whether I am happy or not	.806	Emotional Intelligence
	I always know about my friends' emotions from their behavior	.810	
	I am a good observer of others' emotions	.796	
	I am sensitive to the feelings and emotions of others	.656	
	I have good understanding of emotions of people around me	.817	
	I always set goals for myself & try my best to achieve them	.608	
	I believe I am a competent person	.614	
	I am a self-motivated person	.620	
	I always encourage myself to try my best	.627	
	I am able to control my temper & handle difficulties rationally	.775	
	I am quite capable of controlling my own emotions	.812	
	I can always calm down quickly when I am very angry	.585	
	Try to actually experience the emotions that you must show to customers	-.767	
	Work hard to feel the emotions that you need to show to customers	-.910	
	Make an effort to actually feel the emotions that you need to display towards customer	-.926	
	I generally know what customers want before they ask.	.754	
	I am inclined to read the customer's body language to determine how much interaction to give.	.767	
	I enjoy delivering the intended service on time	.780	
	I find a great deal of satisfaction in completing tasks precisely for customers.	.822	
	I enjoy getting to know my customers personally	.680	
	I actually feel the emotions that I need to show to do my job well	.905	
2	Put on "mask" to display the emotions that manager demands.	.876	Emotional Labor Acting Strategies
	Put on an act in to deal with customers in an appropriate way	.772	
	Fake a good mood when interacting with customers	.867	
	Just pretend to have the emotions needed to display for job	.726	
	I fake the emotions I show when dealing with customers	-.766	
	I put on a mask to express the right emotions for my job	-.818	
	The emotions I show to customers match what I truly feel	-.744	
	I behave in a way that differs from how I really feel	-.822	
	I have to cover up my true feelings when dealing with customers	-.615	
	I show the same feelings to customers that I feel from inside	.823	
3	I have good control of my own emotions.	7.501	Customer Orientation
	I enjoy nurturing my customers.	.821	
	I take pleasure in making every customer feel special	.890	
	Every customer problem is important to me.	.898	

Component	Item	Score	Dimension
	I thrive on giving individual attention to each customer.	.899	
	I can easily anticipate customers needs	.867	
4	I have a good sense of why I have certain feelings most of the time	.741	Recognition-Accurate Self Assessment
	I have good understanding of my own emotions	.753	
	I really understand what I feel	.718	
5	Put on a “show” or “performance” when interacting with customers	.916	Surface Acting
6	My interactions with customers are very robotic(fake)	.791	Emotional Dissonance/ Job Strain
	I display emotions that I am not actually feeling	.853	

The above table shows 6 dimensions that were identified through factor analysis. They were emotional intelligence, emotional labor acting strategies, customer orientation, self awareness, surface acting and emotional dissonance or strain. These dimensions were further tested through mean test. The scores of which are mentioned below.

3.6 Summary: Dimensions and Mean

Sr. No.	Dimension	Mean Score
1	Emotional Intelligence	2.11
2	Emotional Labor Acting Strategies	2.60
3	Customer Orientation	1.73

4	Recognition (Accurate Self Assessment	1.84
5	Surface Acting	1.12
6	Emotional Dissonance/ Job Strain	3.99

From the above analysis it could be interpreted that employees indulge more in surface acting as their mean score is 1.12 which is less than all the dimensions. Hence employees do more of surface acting when interacting with hotel customers. The other dimension which leads to emotional labor is customer orientation as the mean score for it is 1.73 followed by employees self recognition as the score is 1.84.

Hypotheses Testing and Discussion

We have tested certain hypothesis using Mann Whitney test in terms of a demographic factor such as gender and the results are presented in the table below:

Hypotheses	Scores	Remark
Ho: There is no significant difference gender wise in the opinion, “Put on a “mask” to display the emotions that manager wants you to display”.	.014	As the value is less than 0.05, we reject the null hypotheses and conclude that there is a difference in the opinion, “Put on a “mask” to display the emotions that manager wants you to display” and gender.
Ho: There is no significant difference gender wise in the opinion, “Put on an act in order to deal with customers in an appropriate way”.	.000	As the value is less than 0.05, we reject the null hypotheses and conclude that there is a difference in the opinion, “Put on an act in order to deal with customers in an appropriate way” and gender.
Ho: There is no significant difference gender wise in the opinion, “Just pretend to have the emotions you need to display for your job”.	.019	We reject the null hypotheses and conclude that there is a difference in the opinion, “Just pretend to have the emotions you need to display for your job” and gender.

Gender differences

	Put on a “mask” to display the emotions that manager wants you to display		Put on an act in order to deal with customers in an appropriate way		Just pretend to have the emotions you need to display for your job	
Never	Male	Females	Male	Females	Male	Females

	51.1%	48.9 %	43.2%	56.8%	43.1%	56.9%
Rarely	60.0%	40.0%	62.8%	37.2%	66.7%	33.3%
Sometimes	65.1%	34.9%	100.0%	.0%	59.1%	40.9%
Very Often	100.0%	.0%	100.0%	.0%	62.3%	37.7%
Always	100.0%	.0%	100.0%	.0%	80.0%	20.0%

100% male employees always “put on the mask when displaying emotions that managers want them to display”. 80 % of the male employees “just pretend to have the emotions that they require for displaying in their job”. Male employees are more involved in surface acting than female employees.

4. DISCUSSIONS

In the service organizations particular hospitality industry the success and survival of its business depends on their employees. Hence employees are expected to show certain positive feelings towards customers. The results revealed that employees do more of surface acting. The hotel managers must create the situation where employees have to show less of surface acting. This could be done by giving them training and creating supportive system. Proper care must be taken while recruiting hotel staff so that surface acting is not required but deep acting. Hotel management must internalize the process so that employees exhibit deep acting when delivering services to the customers. As a personal resource customer orientation may serve as an antidote to the detrimental effects of job demands leading to delivery of superior customer service. Hotel administration must regulate the emotional display by employee's through periodic trainings to make them skilled in smiling in a truthful manner and for modification of their personal rage into public concern.

A Review on Stabilizing the Manufacturing of SEEOM by Work Study

Jitendra M Patel, Kinjal Suthar

Department of Mechanical Engineering, PIT, Parul University, Vadodara, Gujarat, India

Abstract: Work study is the techniques which is used to find the best way to do any activity. Work study is concept used to increase productivity of process by reducing different wastes like unnecessary moment, inventory, rework, over processing and transportation. It reduces work in progress. Work study is combination of method study and time study. This paper will be using both techniques which can optimize the productivity. In this paper work study technique is studied to stabilizing the production flow of SEEOM (Stored Energy Electrical Operating Mechanism) in industry. 5S is used to organize the workplace.

Keywords: Work Study, Time Study, Method Study, 5S

1. INTRODUCTION

SEEOM stands for Stored Energy Electrical Operating Mechanism. It is electrical operating device. It is mounted on the circuit breaker which are available in 3-Pole and 4-Pole variety of different rating ranging for 40A to 630A. SEEOM is used to operate Circuit Breaker from remote area. Mainly two type of SEEOM are assembled DN2 SEEOM and DN3 SEEOM. It is mainly used in large projects including marine application like navy.

2. LITERATURE SURVEY

Soumya R. Purohit et. al., 2015 explained how they were facing many problems in industry like overcrowded place, time waste in searching for tools, excessive stock, unwanted things, and Conditions go back to their old undesirable levels even after companywide implementation of 5S. 5S system is a starting point of all improvement efforts to drive out waste from the manufacturing process and ultimately improving a company's productivity by improving products and services and lowering costs.

Vipulkumar C. Patel et. al., 2014 used 5S methodology to solve the problems of a ceramic industry in India with the aim of increasing the efficiency of processes and eliminating wastes from the company. Their objectives was to reduce waste from process, one piece flow, maintaining quality level and reduce processing cost. By implementation of 5S and visual management system (GAMBA), there was increase in productivity, improvement in space utilization, employees safety, chances of error reduce and improved inventory management system, cleanness of machines and tools, improvement of the work environment, eliminating chances of accidents in the company. By implementing 5S, 12.91% sq. ft. space in the storage department was saved, as a result movement of men and material was also reduced.

A. Sai Nishanth Reddy et. al., 2016 were having assembly line balancing problem. Objective was to increase the productivity and re-design the layout of assembly line. They compare the actual assembly with new assembly by simulation in Arena software. They used time and motion study to calculate current time of assembly and to improve assembly. 363 seconds was reduce to 198 seconds to produce one unit of study lamp. The production line output increase from 69 units to 127 units. The line efficiency increased from 61.25% to 91.66%. The idle time decreased from 0.179 hours to 0.016 hours and the balance efficiency increased from 55% to 91%.

Ankit P. Vekariya et. al., 2015 studied assembly of diesel engine manufacturing unit. They found that there was no standard time for each operation and all work was done manually by workers and some operations sequences were not proper. By carrying Time Study in Industry all operations were breakdown into small activities and time for each activity was calculated. Process was also study by method study and new layout was proposed. Using MOST technique, proper operation and its sequence were found. By using time and method study material movement and flow of material has been improved. Efficiency of process was improved by 7.70% by time and motion study method and most analysis.

Dr. M. P. Singh et. al., 2016 did time study method which lead to reduction in process time, labor cost and production cost. Major problem were using old technology, manually finishing product, unfinished product from vendor. New technologies are used to reduced production cost, process time, cost and energy consumption after using method study. Improved layout and flow process chart and new devices are suggested using recorded observation and discussion with manager of the company.

Mr. Sujay Biswas et. al., 2016 states about excess material is removed manually after blow molding process. Due this problem they were not able to complete the work in time. Work-study is the most effective tool to increase productivity because it considers all the factors affecting productivity. By method study, most effective method of performing the job can be determined by layout improvement and by one piece flow. Work measurement will help to find time required to make a job in standard time at specific level of performance.

Mihir B Patel et. al., 2015 point out after studying several paper that work study techniques can be used to reduce the cycle time but also in various other departments in industries like inventory control, productivity, quality, labor work, at various machines in machine shop to get process variation etc.

Mr. Sujay Biswas et. al., 2016 emphasized on productivity improvement with the help of work study technique combined with motion and time study in the manufacturing enterprises. The work study technique is used by the manufacturing enterprises to reduce work in progress, inventories and waste of resources like man, machine, materials, space, etc. They only study work study technique and how to implement in industry. They conclude that work-study is the most effective tool to increase productivity because it easy to understand and can be used easily.

Ishwar Bhiradi et. al., 2014 worked on improving productivity of mixed model production system of a medium scale manufacturing industry using work measurement approaches. The work measurement of various activity of the work cycle has been taken. The work cycles were divided into small measurable work activities. These activities were recorded on the observation sheet. They also used time study and motion study to understand the various movement during process. Then all the non-value added activities has been removed. As a result there is 35% improvement in productivity.

Patange Vidyut Chandra 2013 applied work study technique. Here work study technique is studied along with time study and motion study. It gives the scopes of using work study technique in manufacturing industry. It explains the effect of work study technique on productivity, labor and workplace.

R. Hedman et. al., 2013 explained about using work study data in automated company to fully utilize the human resources. By this full capacity of the human and machine can used and productivity of company can be increased. If it is implemented in manufacturing models it will contribute to improve planning, control and execution of production. It will also assist and encourage production improvement initiatives.

Prof. S. B. Khedkar et. al., 2012 used 5S technique in a plastic molding company. Stepwise 5S was applied and all the unnecessary things where removed. Productivity increases, better space utilization, clean working area, standardization of process, PEEP application, etc can be achieved by 5S . By implementing 5S cost of production also decreases, decrease in sudden breakdown and increase in morale.

Mst. Murshida Khatun 2014 explained that there are varieties of garments produce in industry, so time study and method study is used to study the process. By using time study standard time required to make an individual garment is noted. Same way standard time for all different type of garments are find out using time study. Using motion study, motion of man, machine and material is studied and unwanted motion was eliminated. By making the time and motion study productivity can be maintain.

Shuang Lan et. al., 2009 used work study as they facing problems like bottleneck process and unbalance line. After the work study, different steps for improvement were taken, so the yield of A model lighting assembly line was increased from 9.97pcs to 12.19pcs. It reduced the operation time of the processes and eliminated the bottlenecks from processes. It enhanced the continuous production system. The number of workers was reduced from 21 to 18. The cost was reduced slightly.

Reda Tajini et. al., 2014 used work measurement technique. They used MTM and chrono-analysis to measure the work in two different ways. The chrono-analysis is an analytical method but it requires a lot of resources and time. The MTM is a fast method which is based on the time standards and the basic elements. The results obtained by both the methods were different. It is help full to identify number of workstations required in company.

Rishabh Mishra 2015 explained that how method study can be used for process improvement like work procedure and proper utilization of machine and material. It help to improve the current status of process and it reduces transportation and reducing worker's fatigue. By using method study productivity can be increased. After applying method study results weekly production increase from 560 to 588 per week.

H. Sabatini et. al., 2010 explained that how time study is a effective tool for detecting and reducing the cycle time losses in assembly line. Time study methodology helps us to calculate time for each activity in assembly. By using method study material handling can be reduce. Different lean can easily be identify. Time study and Method study help to eliminate lean waste from assembly line when used them proper other lean tools like 5S.

3. METHODOLOGY

3.1 Work study

“Work study is a generic term for those techniques, particularly method study and work measurement, which

are used in all its context and which lead systematically to the investigation of all the factors, which effect the efficiency and economy of the situation being reviewed in order to effect improvement.”

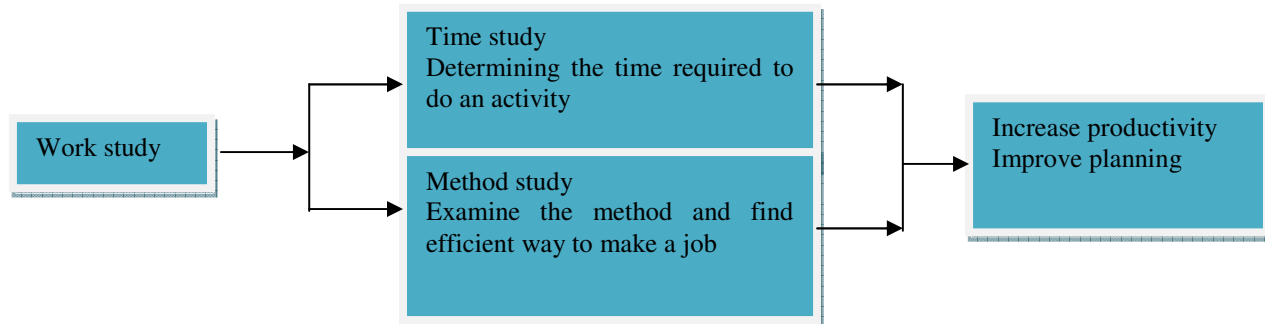

Fig: - 3.1 work study classification [Mr. Sujay Biswas et. al., 2016]

3.2 Time Study

Definition of time study is: “The art of observing and recording the time required to do each detailed element of an industrial activity/operation.”

Scope of Time Study

- Time required to make a job can be find out
- Comparison between different method can be done to find most efficient method by using time study
- Proper line balancing can be done
- It can help to analyze the process to reduce or eliminate unnecessary activities

3.3 Method study

Method Study may be defined as: “A procedure for examining the various activities associated with the problem which ensures a systematic, objective and critical evaluation of the existing factors and in addition and imaginative approach while developing improvements”.

Scope of Method Study:

- Quality standards
- Movement of material and tools
- Material to be used
- Cycle time

3.4 5S

‘5S’ is a workplace management methodology which helps to improve the working environment, human capabilities and thereby productivity. The word ‘5S’ represents the 5 discipline for maintaining visual workplace

1S Seiri (sorting):- classify wanted and unwanted things and removing unwanted things

2S Seiton (set in order):- it means set in such a way that there is neither extra motion nor any difficult in accessing the materials.

3S Seiso (shine):- always keep workplace and tools clean

4S Seiketsu (standardize):- define standard method for every process

5S Shitsuke (sustain):- Maintain consistency in the method of doing work

4. CONCLUSION

Work study includes time study and method study. work study is used find all factors affecting the production system. Work study help to identify and eliminate the waste like rework, work in progress, inventory, etc. By using method study various activities associated with the problem can be examine and ensures that work is done as per stated sequence. It will help to find most efficient way of doing work. Time study help measures the required time to perform the any activity. Standard time of each activity can be find out by time study. By using 5S, work place can proper be organized. Work study along with Time, Motion study and 5S can be very useful to stabilize the productivity of product, to calculate standard time of each process, reduce waste, organizing the workplace.

Designing a Framework for Occupational Health and Safety as per Indian Context

Faisal Firoz, Suchismita Satapathy, Debesh Mishra, Jitendra Narayan Biswal, Sonam Patel

School of Mechanical Engineering, KIIT University
Bhubaneswar, Odisha, India

Abstract: Government is concerned about the safety of employee in a industries as its the top most priority for the sustainable development of the organisation as well as to create a friendly and healthy environment to work. Indian Government is implementing different laws and regulations concerning occupational safety and health and to secure the working environment and also implementing an adequate and appropriate system of inspection as the workers or the employees' safety is the top most priority for every industry. The purpose of this paper is to review research in the health effects and risks associated with the different industries like steel automobiles mining manufacturing sector and others like construction and to design a framework for these factors related to the occupational health and safety practice with the QFD tool. The important theme of this research is to propose a framework providing guidelines for the managers in policy formulation to improve safety performance as an essential concept of injury prevention social marketing

1. INTRODUCTION

To minimize the health hazards, organizations usually implement an occupational health and safety (OHS) policy authorized by the organization's top management clearly stating overall OHS objectives and demonstrating commitment to improve safety performance. The organizations establish, implement and maintain documented procedures for hazard identification, hazard/risk assessment and control of hazards/risks of activities. The methodology adopted for such activities is based on operational experience. However, identification of risks and remedial measures in procedural format is difficult to establish and varies with contextual environment.

2. BACKGROUND

Taking precautions against the risks and hazards in the workplace is one of the basic tasks of people with management responsibility. Efforts to provide safety in workplaces are not only significant for the health of workers but also inevitable managerial activities for economic and financial performance, productivity of the facility and the quality and stability of production (Fernández-Muñiz et. al. 2007). Furthermore, risk assessment is an essential and systematic process for assessing the impact, rate and the penalty of human activities on systems with hazardous characteristics and constitutes a needful tool for the safety policy of a company. The variety in risk analysis procedures is such that there are many suitable techniques for any situation and the choice has become more a matter of taste (Rouvroye and van den, 2002). A good number of research works have been done for assessing risk in construction industries by traditional tool like probabilistic risk analysis, fault tree

analysis, etc. based on historical data. The work by (Hauptmanns et al., 2005) based on fault tree theory, is the systematic procedure to perform a quantitative risk assessment for occupational accidents. According to (Faber and Stewart, 2003) risk is defined as the expected consequences associated with a given event.

3. RESEARCH METHODOLOGY

The questionnaire used in this study contained twenty eight items and the respondent needed to answer all the items using 1 to 5 Likert-type scale (1-strongly disagree and 5-strongly agree). The responses were collected from managers, safety officers and workers of different departments (both private and public) across the organisation through e-mail/postal/personal contacts. The perceptions on twenty eight items from respondents related to occupational health and safety in the industry types were compiled.

3.1. Result Analysis

Fifty useful responses were tested to examine the validity and reliability of the scale so as to obtain a quantitative and statistically proven identification of the responses. The test for quantitative variable was conducted by factor analysis on 50 responses using the principal component method followed by varimax rotation to ensure that the variables are important and suitable for the model using Minitab 15.0. Twenty two items were categorized under nine social factors constituting various variables for proposed instrument to measure the relation between occupational safety management and firm performance as perceived by safety officers and workers. These nine social factors are defined as Preventive procedure, OHS training, Risk management, Work practices, Periodic plans, Continuous

improvement, Injury avoidance, Emergency plans and Health care. The items that failed to get loaded more than 0.5 were not considered for further analysis. This was true for refer to items 5, 6, 8, 10, 21, and 22. Percentage of total variance explained was found to be 75% which is an

acceptable value for the principal component varimax rotated factor loading procedure. The internal consistency of the actual survey data were tested by computing the Chronbach's Alpha (α). The factor loadings are shown in Table.1.

TABLE 1: Factor Loading Score

Factor	Item No	F1	F2	F3	F4	F5	F6	F7	F8	F9	Cronbach's Alpha
Preventive Procedures	2	.877									.825
	3	.557									
	4	.593									
	13	.892									
OHS Training	9		.626								.782
	10		.683								
	11		.787								
	12		.697								
Risk Management	5			.614							.516
	6			.665							
	7			.578							
	18			.627							
Work Practices	8				.754						.714
	21				.648						
Periodic Plans	19					.748					.760
	28					.774					
Continuous Improvements	7						.517				.656
	15						.853				
Injury Avoidance	16							.613			.747
	17							.820			
Emergency Plan	14								.843		.842
Health Care	20									.888	.788

After getting seven important parameters/items for the improvement of policies of Occupational health and safety by interview with experts, QFD was applied to identify system design requirements for occupational health and safety is studied. Steps of QFD are:

- Customer needs (What's): A structured list of requirements derived from expert's feedback listed in figure 1 left side.
- Design requirements (How's): A structured set of relevant and measurable services/characteristics which are required for fulfilling what are mentioned in figure 1 topside.
- Planning matrix (left matrix): Gives customer/expert perceptions observed in surveys. It includes the relative importance of requirements

- Interrelationship matrix (center matrix): Gives the expert's perceptions of interrelationships between design requirements and customer needs. An appropriate scale is applied and illustrated using symbols or figures. Filling this portion of the matrix involves discussions.
- Design correlation (top) matrix: Used to identify where design requirements support or impede each other in the system or product design.

$$\text{Customer ratings} = Z_i + \frac{1}{n-1} \sum_{j=1}^n (B_{ij} Z_j) \quad (1)$$

B_{ij} is i^{th} initial customer rating and Z_j denote the relationship between customer need and customer rating respectively

n number of customer need
 B_{ij} [B_{1ij} , B_{2ij}].

The individual rating for each design requirement is obtained from the center matrix using the following relation: Design requirement = $\sum_j^n (A_{ij}, X_j)$ (2) Where A_{ij} and X_j denote the relative importance of the i^{th} characteristics with respect to the j^{th} customer need in the relationship matrix and the importance of j^{th} customer needs (customer ratings) and n is the number of customer needs. Table.4 shows Employee requirements and Table.5 explains design requirement. Table.6 shows the symbols used in QFD. Figure1 shows QFD HOQ.

TABLE 4: Employee Requirements Table

1	Preventive measure
2	Emergencies plan
3	Injury avoidance
4	Health plan
5	OHS training
6	Periodic plan
7	Risk Management

TABLE 5: Design Requirement

1	Safety training programs are conducted in the organization on regular basis
2	Instruction manuals being followed before executing any hazardous job activity
3	Immediate medical facilities are provided for personal injuries

4	Alarms/beeping sound/alarming light and emergency lights work effectively when a crisis situation arises
5	A Safety equipment's are supplied by the organization to avoid accidents
6	The company readily provides health subsidies when accidents occur within the workplace
7	The employees works in healthy and safety condition
8	Regular auditing is done by OHS
9	Company undertakes a stress risk assessment in the workplace

TABLE 6. Symbols of QFD

0.8	Strong	0
0.6	Moderate	Θ
0.4	Weak	Δ
0.2	Very weak	

A QFD matrix was prepared, and the respondents were asked to assign numeric relative importance scores to the various customer requirements, from the lowest to the highest, on a scale from 1 to 9. They were also asked to express, in numeric values, the strong-moderate-weak relationship between what's and the How's as .2, .4, .6, and .8 with symbols. After the responses were collected, scores for each of the columns was computed. The design requirements are prioritised as per their importance of design requirement.

Fig. 1. House of Quality

4. RESULT AND DISCUSSION

As OHS is a sensitive issue, the industries are reluctant to share the accident data at least in Indian environment to gain insight into the problem and propose corrective measures. Because of paucity of field data, the study undertakes a questionnaire survey to assess the safety culture in industrial settings. Although the survey uses many safety items (or characteristics), it finds that the items and number of items widely differ across the types of industries, size and location of organizations.

5. CONCLUSION

The instrument developed is useful for improving morale of the workers and their satisfaction in regard to safety issues. The instrument has been tested using statistical tool and can be used for comparative evaluation of safety practices within and/or among organizations. Using the instrument, comparison of various industrial settings has been made using discriminate analysis. An instrument has been proposed to assess OHS practices in Thermal Power Plant

which are characterized by disorganized and unsafe work environment. Although internal guidelines and Government legislation is being practised in these industries, the work practices seems to be below average.

Optimization of Resources through Automation

Rashee¹, Nilanjan Biswas², Goutam Mukherjee³, Rakesh Shrivastava⁴

^{1,4} Productivity Services Department, Tata Steel Limited, Jamshedpur, Jharkhand, India

^{2,3} WRM, Tata Steel Limited, Jamshedpur, Jharkhand, India

Abstract: In today's competitive world productivity improvement is one of the most important initiatives to keep us ahead of competition.

With the increasing competition and change in economic scenario of country surviving & growing in steel sector is becoming tough & tougher. Cost optimization, value engineering, productivity improvement, quality improvement and time management has become the vital tools for the survival, progress and to become an EVA positive organization.

- In this Long product Mill there are three separate Control pulpits as:
- CP1 for controlling billet feeding to the furnace
- CP2 for controlling billet feeding to the MILL (out from furnace)

CP3 for billet movement in different stands of Mill for formation of Wire Rod.

Being located at three different places and being managed by 3 teams there were many incidences of coordination gaps which resulted in chopping off the Billet which was a huge financial loss. Moreover the Mill had to be made down for correction which was again a big opportunity loss.

Another aspect was, in this era of automation and mechanization the manning for this section was a concern. Moreover as per the company's norms relievers in each pulpits were also given separately which was ultimately lowering the productivity and affecting the bottom line of the Company.

This paper deals with the approaches taken in the Long product Mill to identify and resolve the issues related to better coordination of billet movement, Manning optimization and automating the whole system. After a long study and research a decision has been taken for merger of all three pulpits into ONE. Different Industrial engineering Principles & techniques were used in the entire study like work measurement, Facility Planning & Layout Design.

For this idea implementation there were few factors that proved to be hurdle in implementing the ideas identified which included both Technical aspect as well as IR issues. After proper approval the idea of Merging of three pulpits is on its way of implementation. It is proposed to be implemented and functional by 2019 March.

1. INTRODUCTION

Any organization is a combination of many small units that unite and work to achieve a goal together. In a steel plant also there are many interconnected units/plants, starting from planning till dispatch. So it's very important that every unit is so productive enough that overall Plant/company is ahead in the industry's productivity race. In this competitive era we should focus of each and every bit of either reducing waste or improving current practices so that loss can be minimized & profits can be maximized.

2. PLANT DETAILS

- Installed in 1987
- Built by M/s Davy-Mckee, U.K
- Mill consists of
 - Billet processing facilities in Billet yard,
 - Reheating furnace,

- Roughing Mill,
- Intermediate Mill,
- Pre Finishing Mill & Non –Twisting Mill

- Plant capacity: 0.42MTPA
- Facility of online inspection by Process Control is installed with an express lab for quick decisions.
- The Mill has been installed with Profile gauge, Flaw detector, Laying head with front end orientation and Ring distributor

3. PRODUCT RANGE OF THE LP MILL

- The mill is designed to produce 5.5 mm to 20 mm dia. rounds and 8, 10 & 12 mm diameter Rebar
- This mill can produce following quality of wire rods
 - Low Carbon

- High Carbon
- Pre-stressed Concrete
- Electrode quality
- Cold heading quality
- Ball bearing
- Cable armored quality
- High yield strength rebar
- This mill converts the billets into plain wire rods in sizes 5.5mm to 13.0mm and re-bars used in construction segment in sizes 8.0 – 10.0mm. This is done by innovative & analytical approach based improvements in existing Processes/Products and help in maintaining the cost effectiveness

4. LAYOUT OF MILL

5. FORMATION OF WIRE ROD FROM BILLET

- This process starts from Billet inspection. After the inspection billets are placed on the Charging grid by Crane.
- One by one (at an interval of ~90 sec) billets are pushed in Furnace and this activity is controlled and monitored at CP1.
- Charged billets once out from the furnace are sent to Mill. This billet supply to mill is controlled and monitored at CP2.
- Charged billets are passed through different stands of Mill for the formation of Wire rod. This whole process is controlled and monitored at CP3.
- Once wire rod is formed it is passed through Stelmor convener and sent to OS6 (Finishing section)

- The Finishing section then takes care of coil inspection & testing then binding.
- After this Shipping section does the loading and dispatch activity.

6. CURRENT ISSUES AT MILL

The three activities: Pushing billet to Furnace, Feeding charged billet to Mill & Formation of Wire rod from Billet are the most critical (inter-connected) activities.

But monitoring these three at three locations was creating problems. The CP1 operator has no visibility of what is happening in Mill and same with CP2 & CP3, they had no visibility of Billets pushing to furnace. Biggest problem was the coordination gap!

Many times it happens that some sudden problem happen in Mill so the mill had to be stopped. But by the time this message was passed to the CP1 operator he already inserted a billet to Furnace. So there was no other option rather than chopping off the billet. This was a huge Loss.

Area	Working Force	Relievers	Total
CP1	1/shift	1/shift	2/shift
CP2	1/shift	1/shift	2/shift
CP3	2/shift	1/shift	3/shift
Total /Shift			7/shift

Another perspective of this issue was the Manning of Mill. The manning was done pulpits wise and also as per the company norms relievers to all operators were given.

In this era of Automation and Mechanization operating a Mill with so many people was a bottleneck to Productivity.

7. PROPOSED SOLUTION

After a detailed study from all perspectives better coordination of billet movement, Manning optimization and automating the whole system. After a long study and research a decision has been taken for merger of all three pulpits into ONE. Different Industrial engineering Principles & techniques were used in the entire study like work measurement, Facility Planning & Layout Design.

8. IMPLEMENTATION OF PROPOSED CONTROL PULPIT STRUCTURE

- The first step towards this was preparation of plan and budget.
- Approval for capital investment was taken from higher Authorities
- Different agencies were invited for study of plant and give quotation for formation of new pulpits.
- Most suitable vendor was selected and order for new pulpit was placed.
- By March 2018 the ordered pulpit is expected to be delivered which will be installed during next annual major shutdown of plant.

9. CHALLENGES

The major challenge what is visible now is the IR issue. Being an old mill most of the employees are 40+ years of age and for them adopting a new work practice will be tough.

There will be a reduction of workforce as with the merger of pulpit the roles will be merged so instead of current 7/shift we would only need 4/shift for Mill operation. So this reduction implementation has to go through some Union discussion and finalization.

10. CONCLUSION & BENEFITS

For the successful implementation of a proposed structure, the organization's objectives, principles undertaken in designing of the organization structure & HR issues need to be carefully considered.

There will be multiple benefits after this new pulpit installation

1. Saving of billet wastage
2. Opportunity loss reduction: As the mill has to be made down for chopping off the charged billet
3. Manpower cost reduction

Review of Habits of Mind Using Teaching Pedagogies for Analyzing Thinking Strategies in Engineering Education Classroom Teaching to Improve its Performance

Aashish Gandigude

Department of Mechanical Engineering,
Zeal College of Engineering and Research, Pune, Maharashtra, India

Abstract: Deficiencies in engineering education have been exhaustively exemplified in past few years. Higher education is becoming a major driver of economic competitiveness in an increasingly knowledge-driven global economy. The focus of engineering education is shifted in last decade around designing course with outcome based learning and employability for students. The contemporary attention of higher education institutions is weighed on the basis of its national and international rankings. And these comparisons tend to overemphasize research, using research performance as a yardstick of institutional value. If these processes fail to address the quality of teaching, it is in part because measuring teaching quality is challenging. With this comprehensive wish list it will be highly difficult to design engineering curriculum so that the average student can complete his graduation in four years. The present paper is an attempt to summarize bridge gap through design of effective teaching pedagogies in order to provide engineering solution to real world problems.

Keywords: Classroom Teaching, Habits of Minds, Engineering, Pedagogy

1. INTRODUCTION

If one could try to define engineering or what an engineer is, we will all come up with similar answers as ‘engineering is the application of science’ or ‘the use of science and mathematics for solving technical problems’, or ‘Engineering is the science, skill, and profession of acquiring and applying scientific, economic, social, and practical knowledge, in order to design and also build structures, machines, devices, systems, materials and processes’ and anyone who practices engineering is called an engineer.

The US Accreditation Board for Engineering and Technology (ABET) has also similar kind of definition: ‘The creative application of scientific principles to design or develop structures, machines, apparatus, or manufacturing processes, or works utilizing them singly or in combination; or to construct or operate the same with full cognizance of their design; or to forecast their behavior under specific operating conditions; all as respects an intended function, economics of operation or safety to life and property’.

Plato (2013) [17] has established relationship of engineering with other disciplines as illustrated in Figure 1.

Fig. 1. Engineering is applying science for creating our physical world.

2. SURVEY:(FOR CLASSROOM TEACHING)

This paper surveys few instructional summarize methods and pedagogical techniques that extends engineering theories beyond the realms of classroom teaching.

2.1 Formulate, publish and communicate instructional objectives clearly: [1–10]

The board of studies brain storms to formulate the course objectives, which in later is published by course teachers to communicate it effectively to the students.

This way an instructor items the list of instructional objectives with detrimental goal. And the measurement

criteria should be included for defining statement in following manner.

Bill Lucas et.al (2016) identified six Engineering Habits of Mind (EHoM) to cultivate them in class rooms using four pedagogies.

Claxton et. al, (2016) suggested ways of finding, developing and improving which causes confusions for educating employable engineers.

Heckman & Kautz, et.al (2012) investigated the individual potential for enhancing the individual success in the market for long term through soft skills.

Example: Course Objective for Engineering Metrology:

Students are expected to-

1. Select suitable instrument/gauge/method of inspection for determining geometrical and dimensional measurements.
2. Calibrate measuring instruments and also design inspection gauges.

Course Outcomes for Engineering Metrology:

Students should be able to-

1. Select measuring instrument, carry out data collection and data analysis.
2. Design gauges required for inspection purpose.

2.2 Inductive Vs Deductive approaches of Teaching:

These approaches of teaching works exactly in contrast to each other. In inductive approach students generalize theories based on common elements of collected information. Whereas, in deductive approach students collect information based on general theories. This contrast in approach is explained in fine manner with following figures:

Fig. 2. Contrast between Inductive and Deductive approaches of teaching

Example:

Case-I: A group of students assigned to jot down the ideas based on topics covered during classroom teaching for design of pipes.

Case-II: Another group of students assigned to design piping system for boy's hostel from central tank.

The very common and famous inductive teaching pedagogical tool in higher education is project based learning (PBL). Wherein, the group of students built their project around real world problems. Many researchers [11-13] have highlighted this as an effective tool in the field of science and technology.

2.3 Inculcating culture of Active Learning in the Classroom through Cooperative Learning Approach:

Cooperative learning approach is rapidly growing instructional method in engineering education due to its effectiveness [14-16].

Fig. 3. Inculcating Cooperative Learning in the Classroom

Example: Assigning groups for completing laboratory reports, projects, and assignments in courses.

3. LITERATURE SURVEY:(FOR TEACHERS)

This section of paper deals with class room habits and flow of information those are made by teacher during class room teaching.

Wood and Runger et. al, (2016) demonstrated effectively the class room behaviors of students are helpful for individual progress and their workplace.

Lally and Gardner et. al, (2013) suggested to trigger individual through reward for class room responses. This key repetitive habitual action encourages class room habits.

Bloom and colleagues et. al (1984) defined six levels of instructional objectives as per following manner:

Fig. 4. Six levels of instructional objectives

The levels 1–3 are commonly known as lower-level skills and levels 4–6 are higher-level skills. UG level skills focus on 1-3 level whereas, as per ABET engineering accreditation criteria involves higher criteria skills.

4. CONCLUSION

This paper is an attempt to identify budding engineer's habits of mind to know more about their thinking strategies during classroom teaching. These habits of mind can be strongly planned with effective class room pedagogies to solve real world engineering problems.

Abstract: The aim of this paper is to find out the Determinants of Employee Satisfaction in EPC companies that are engaged in Oil and Gas Industry in Middle East. The current trend of low Oil prices have forced EPC Companies in Oil Industry to restructure their sizes resulting in number of persons losing their jobs. This has resulted in low level of Employee Satisfaction. A satisfied employee will definitely be inclined to put his best show which naturally would enhance the chances of a company in achieving its various business parameters. Since EPC companies work on time bound projects and with stiff competition, this study assumes importance. Selected Sample from EPC companies in Oil Industry was surveyed. The results proved that the current Employee Satisfaction level is lower than the Middle East standard as well as Global standard. The Determinants of Employee Satisfaction is also found out.

Keywords: Employee Satisfaction, Oil and Gas Industry, Middle East

1. INTRODUCTION

Satisfied Employees are vital for the success and performance of an Organization. According to Rust et. al, (1996), Employee turnover is inversely proportional to Employee satisfaction; i.e. increase in Employee Satisfaction will lead to reduction in Employee turnover and vice-versa. The Latest study conducted by Gulf Business (published on 3.6.2015) states that in UAE around 53% of the employees are having low level of satisfaction.

The EPC Companies work on a tight budget and time schedule. If they fail to complete the project in time, they will have to pay liquidated damage (LD) or penalty which generally goes up to 10% of the contract value. Further, they also will incur additional cost due to extended stay. This will affect the companies' performance and considerable negative effect in the bottom line. Each and every project handled by EPC companies is unique in nature. The persons involved are required to deliver their portion of work till completion of the project. If some employee leaves at middle of the project, the replacement employee will take considerable time to understand the project and to start delivering his / her duties. This will affect the time schedule of the project.

A study conducted by Abubakr M. Suliman Hanan et.al., (2011) concludes that recruitment and retaining of employees has become one of the main problems faced by Middle East Countries. They state that the staff turnover costs in organizations operating in UAE costs about AED 9.9 billion a year. The study confirms that the current organizational climate is discouraging and it negatively

affects employee satisfaction level. This in turn may hasten employee turnover.

Elisa et al., (2001), in their study state that costs to the organization for an expatriate employee returning home prematurely have been estimated to range between USD 100, 000 and USD 500, 000, and nearly 20% left their organization only to work for a competitor after returning home.

The EPC Companies in Oil Industry work on a tight timeline and budget. Due to the reduced level of Employee Satisfaction, employee turnover shall increase resulting in:

- Revenue loss for the companies due to replacement cost
- Revenue loss due to companies' extended stay in the project.
- Revenue loss in the form of Liquidated damages and Penalties levied by Clients
- Revenue loss due to less productivity from the existing dissatisfied employees
- Non Revenue Loss due loss of reputation / goodwill in the market
- Losing of future contracts due to above factors.

Hence the study of Employee Satisfaction in EPC Companies of Oil Industry in Middle East assumes great importance. The paper is aimed at finding the determinants of Employee Satisfaction of EPC Companies engaged in Oil and Gas Industry in Middle East.

2. LITERATURE REVIEW - EMPLOYEE SATISFACTION

A detailed Review on existing Literature was conducted to find out the determinant of employee satisfaction. Bakr Ahmed (2008) states that diversity is positive factor which leads the firms to be healthy and it creates competitive advantages for firms. According to Jasna et al (2011), the very important characteristics of an organizational support favorable to employee satisfaction include giving employees discretion on work, giving a patient ear to his employees' suggestions/grievances, rewards, training, management support, trust, free intra-organizational boundaries, commitment and involvement in their personal welfare.

Muhammad Eshan Malik et al. (2011) splits his findings into two parts - one on the employee's retention and the second one on employees turnover rate - he concludes that while organizational culture, promotions, training practices and hiring of the personnel have directly influence on employee's retention; the organizational goals, its missions (in giving importance to employees' suggestions), rewards given to employees, compensations (provided to employees' well being) and recognitions (highlighting their achievements) positively decrease turnover rate of the employees.

John Sutherland's (2013) study emphasizes that personal characteristics such as gender, age and education and also to job characteristics such as hours worked, training provided, promotion prospects, and establishment size play significant role in arriving at the job satisfaction. Benjamin Artz, (2010), argues that job satisfaction is inversely related to job absenteeism, turnover and directly related to output. Aysit Tansel and Saziye Gazioglu conducted a study in 2013 titled "Management-Employee Relations, Firm Size and Job Satisfaction". They found out that a good relationship between management and employee is necessary for a satisfactory organizational performance of an organization and for its human resources to feel that they are being effectively engaged.

Carolyn Stringer et. al., (2011), find that intrinsic motivation and satisfaction with one's pay have a direct bearing on employee satisfaction, whereas extrinsic motivation has a negative association with employee satisfaction. Aon Hewitt (2014) observes that Middle Eastern organizations have the tendency to push their growth and profitability targets further and putting the economic crisis in their back yard without the thought that it imperative for an organization to retain the required talent to achieve their ambitious goals. Yousef (1998) opines that the employees (expatriate) in Saudi Arabia are not pleased with their job security.

Kuehn et al. (2002) found that Omani employees reported relatively high levels of both satisfaction and commitment

as compared to expatriate workers, particularly in the private sectors. Alizee B Avril et al., (2007), in their study disclose that main reason for an expatriate to fail in his / her assignment is the incapability of the expatriate's spouse to get adjusted in his / her new surroundings. The expatriate has a sense of belonging at the work place where as the spouse often struggles with feelings of alienation. Okpara et. al., (2011), summarized that from 10% to 80% of expatriate employees who were sent on foreign assignments were returning home before completion of their assignment. This is costing multinational enterprises (MNEs) in the range of U.S.\$ 40, 000 to U.S.\$ 1 million for each failed assignment. The main reason for expatriates' failure is identified as their incapability to adapt themselves to the host-country's culture.

3. THE PRAPOSED METHODOLOGY TO FIND OUT THE DETERMINANTS OF EMPLOYEE SATISFACTION FOR EPC EMPLOYEES WORKING IN OIL INDUSTRY IN MIDDLE EAST

The Research Methodology proposed for the Study

Objective	To find out the determinants of Employee Satisfaction in EPC Companies that are engaged in Oil and Gas Industry in Middle East
Research Design	Descriptive Research Study
Observational Design	1. Variable Identification through Literature Review (Various Facets of Employee Satisfaction) 2. Preparation of questions asking the respondents to list the factors contributing to improve satisfaction 3. Pilot testing of the Questionnaire 4. Administering the Questionnaire to the selected Sample 5. Conducting Structured Interviews with top level management of selected EPC Companies
Sampling Design	Employees' Portion of Sample Stratified Proportional Sampling (strata based on Large, Medium and Small EPC Companies) to select the number of companies in each strata. Within each company the sample size was decided which was proportionate to their Middle East staff Strength. The sample selection for the decided strength within the company was based on disproportionate stratified sampling Sample size estimated based on Taro Yamane's formula was 100 and Sample size Obtained is 93

Objective	To find out the determinants of Employee Satisfaction in EPC Companies that are engaged in Oil and Gas Industry in Middle East
	Employer's Portion of Sample The EPC companies were stratified as Large, Medium and Small. Since the Employees of Large Companies will have good satisfaction level, they have not been selected in the sample. One Medium size Company and Two Small size Companies were selected. Top Level Employees of these Companies were interviewed to get their inputs on changes that are needed to improve Employee Satisfaction
Data Analysis	Descriptive Statistics. Tabulation of results by combining the responses from Employees and Employers

4. EMPIRICAL STUDY

In this section, an empirical study is presented in which the determinants of Employee Satisfaction of EPC Companies that are engaged in Oil and Gas Industry in Middle East was found out. 93 Respondents provided suggestions

containing 279 suggestions in total. These were grouped under 21 parameters. The following are the improvements suggested by the Employees for enhancing Employee Satisfaction:

4.1 Problem Description

There is a huge Business loss due to Employee turnover. The Employee replacement cost also amounts to loss for the organization. Addin to the above, the EPC companies face problems such as tight work schedule and stiff competition. Success can be achieved by them only if they improve their edfficiency. One of the means to improve efficiency is retaining talent and motivating them to deliver their best. This can be possible with improved Employee Satisfaction. The study is aimed to find out the determinants of Employee Satisfaction in EPC Companies that are engaged in Oil and Gas Industry in Middle East.

4.2 Findings of the Study

The findings of the study revealed that the current level of Employee Satisfaction of EPC Employees is much lower at 5.7 when measured on a 10 point scale compared to Global Standard of 7.2

The chart below provides changes that are suggested by respondants to improve Satisfaction level:

Fig. 1. Changes Suggested to improve Employee Satisfaction

38.71% Respondents felt that Training is very important for employee satisfaction followed by Salary increase (27.96%) and closely followed by Appraisal & feedback (25.81%), Fringe benefits (24.73%), working hours (22.58%) and Team Building (19.35%). Incentives & Rewards (18.28%), Communication (13.98%), Equality (12.9%), Recognition (11.83%), Clarity of vision / mission (10.75%), Appreciation (10.75%) have been placed at a correspondingly lower level.

It is interesting to note that Employees have given very less importance to Promotion (9.68%), Good treatment (9.68%), Motivation (8.6%), Good supervision (8.6%) and career development plans (8.68%). All other heads (4 parameters) have been established as having least importance.

The following table provides the clear view of the respondent's suggestions:

% of Respondents Suggesting improvement factors	Suggested Factors for improving Employee Satisfaction
More than 20%	Training, Salary Increase, Appraisal & Feedback, Fringe benefits and Reduced working hours
11% to 20%	Team Building, Incentives and rewards, communication, Equality, Recognition, Clarity of Vision / mission and Appreciation
Less than 10%	Freedom of work, innovation, career development, good supervision, role clarity, job security, Motivation, Promotion, Special treatment for Project persons

5. DISCUSSION

Since there is a huge cost involved in the separation, recruitment and replacement of employees, it is profitable for the organizations to retain the talent. Further, the EPC Companies in Oil Industry engage in projects which are unique in nature. In such circumstances, the employee engaged in the project does some only-one-of-its-kind type of job unlike a common type of job done by employees of other normal industry. A lot of safety related trainings are involved in the placement of employees in EPC Oil industry such as Safety Induction, H2S training, TBOSIET, First aid etc. in addition to special medical tests. These training and tests are very costly and time consuming. So, replacing an Employee of EPC Company in Oil Industry will not only be a costlier affair but also time consuming. Since these companies will be working on a tight timeline, the delay in replacement (of employee) will lead to project delay as well as loss to the company due to extended stay. This will also create a loss to the end user. Considering the above, it is very much evident that Employee Satisfaction is very important in EPC, Oil Industry. However, the current Employee Satisfaction level is not encouraging. Therefore, it is all the more important for the EPC companies to concentrate in improving the Employee Satisfaction Level.

6. CONCLUSION

The study concludes that the Employees working in EPC companies have very high level of dissatisfaction in areas such as stress level, working hours, equality & respect, recognition and promotional opportunities. The Study also concludes that the Employee Satisfaction level can be improved by providing proper Training to Employees, good salary and increment on yearly basis, 5 days a week,

reduced working hours, periodical performance appraisal, improvement in feedback system. The EPC companies in Oil & Gas Industry of UAE need to look into these aspects. It can be deduced from the above that if the EPC Companies device means and methods to increase the Job Satisfaction of their Employees, it shall have a direct bearing on the Employee Satisfaction resulting in higher retention level and leading to EPC Companies achieve their goal of higher productivity, increase in profitability etc.

^{2, 3, 4}Department of Production Engineering, Government Engineering College, Bhavnagar, Gujarat, India

Abstract: This case study is based on one of the wire making industries in south Gujarat GIDC. The main purpose of this paper is to study and understand importance and core consequences of lean manufacturing system and agile manufacturing system in the industries. Today's globalization of low cost market and dynamic demand of customers in this scenario it is important to adopt lean manufacturing and agile manufacturing system and sustain the today competition. In this case study we carried out huge literature survey on lean manufacturing system and agile manufacturing system and understand its importance and study how to implement in wire making industry by use of ideal time study data system. To implement agile manufacturing system and its quality tools it is important to implement first lean manufacturing system. Now based on observation and literature survey we study the whole system of our selected industry. And we show the wire mesh machines are representing low productivity compares to their capacity. So we carried out ideal time study on that machine and identify many problems but, when we study that data we see that one of those problems is cross wire shortage which is caused by wire straining machine so we also carried out ideal time study of that. By ideal time study data of wire mesh machine, we identify some core problems which are possibly responsible for their low productivity and which are as follow (cross wire shortage). Now, we also identify some problem from ideal time study data of ST machine and which are as follow (wire mesh). The lean and agile manufacturing has many benefits because they impact on whole system both technical models as well as on management model. The lean manufacturing system is eliminate the major wastes which are very important, and on other hand agile manufacturing system induce flexibility in industry. So, that industry easily handle huge work load during peak load hours without compromising the quality. This paper represents the time study analysis of the organization which will help the organization to increase the agility.

Keywords: Agility, lean manufacturing system, agile manufacturing system

1. INTRODUCTION TO AGILE MANUFACTURING

According to Oxford dictionary, lean means “strong” and “efficient”. The other meaning mentioned is “thin and fit”. At the beginning of twenty-first century lean manufacturing system was introduced. Lean manufacturing is all about eliminating the various wastes in systematic manner. Lean manufacturing professionals have so far identified as many as nine wastes that occur in organizations (Sullivan et al., 2002; Dahlgaard and Dahlgaard-park, 2006) namely Overproduction, Unnecessary inventory, Delay, Transportation, processing, Unnecessary Motion, defective parts, underutilization of people and Underutilization of facilities. Lean manufacturing professionals have so far identified as many as nine wastes that occur in organizations (Sullivan et al., 2002; Dahlgaard and Dahlgaard-park, 2006). Now, lean manufacturing paradigm enables an organization to achieve high degree of quality and productivity through waste elimination due to customer's dynamic demands. Hence, organizations are required to adopt flexible strategies. On realizing this requirement first of all “agile manufacturing system” introduced. “Agile manufacturing is paradigm that enables an organization to quickly react in accordance with the dynamic demands of the customer by making use of appropriate technologies and management models.” Agile

manufacturing system prefer the cell production method because it's very easy to evolve in the task of meeting customers dynamic demand within the short time duration without compromising the quality, productivity and profitability and all the employees becoming the team members of this manufacturing cells. The researchers have found out that numerous technologies and management models have to be adopted to implement agile manufacturing paradigm (Sharifi and Zhang, 2001). This process will also lead to the intellectual summation of flexible manufacturing system and lean manufacturing paradigm (Sarkis, 2001). The principles of agile manufacturing were formalized, several researchers have identified the criteria that would establish agile manufacturing environment. Most of these researchers enumerated management-oriented criteria for attaining agility in organizations. Agile manufacturing criteria have been grouped into four criteria under titles: management driver, “technology driver”, “manufacturing strategy driver” and “competitive driver”. These groups are arranged in the ascending order of the quantum of the resources required for their implementation.

2. LITERATURE REVIEW OF AGILE MANUFACTURING

A new agility development method for dealing with the interface and alignment issues among the agility drivers,

capabilities and providers using the QFD relationship matrix and fuzzy logic.(Yi-Hong Tseng, Ching-Torng Lin.2011). A conceptual model, based on joint research, which has been developed to identify where UK's best practice companies are in their quest to become agile manufacturing organizations. In support of this, a questionnaire has been developed and completed by best practitioners of manufacturing, to assess the model, and establish whether they are making progress to becoming agile manufacturing organizations (J.M. SHARP, Z. IRANI, S. DESAI. 1999). The role of inventory and capacity in accommodating such variation and identifies how TRIZ separation principles and TOC tools may be combined in the integrated development of responsive and efficient supply chains. A detailed apparel industry case study is used to illustrate the application of these concepts and tools (R.Stratton, R.D.H.Warburton.2003).

GECMAe's agile manufacturing experience is reported, including a list of recommendations for improving its competitiveness. In addition, a framework has been formulated to highlight some important areas and to offer solution alternatives not only to the current problems but also to the ones that may be encountered in the future (A.Gunasekaran, E. Tirtiroglu, V. Wolstencroft .2002). The management strategies and the methodologies to be used on

the pathway to fully implement lean manufacturing will be discussed, taking into account mound making companies classical constraints(P. Peças, E. Henriques, 2003). A conceptual generic model, which covers the quality-based functions and their interrelationships. Implementing the model will assure high quality in the eight quality creation processes of definition, design, development, production, delivery, sales and service, use and disposal/recycle of customized product (A.S.Nookabadiand J.E.Middle. 2004).

3. COMPANY PROFILE

Name: Systematic Steel Industries Limited.

Address: plots 1229 & 1230, Gujarat industrial development corporation, Sarigam, Gujarat.

Products: Armour wire, ACSR wire, Electro & hot-dip galvanized wire etc.

No. of Peoples work: 65

4. DATA COLLECTION AND ANALYSIS

We studied the plant of the industry and we observed that the maximum wastage was carried out in weld mesh plant, so to identify the problem, we study the Ideal time of weld mesh machine and collected the data of weld mesh for 7 days for 7 hours.

5. CONCLUSION

From the collected data we found that the Shortage of cross wire and Shortage of Raw material are the major problem

for the brake down of weld mesh machine. By data analysis we came to now that the major problem or brake down phase by us is due to cross wire shortage from data collection for weld mesh shortage of cross wire is 15.51%,

6. RECOMMANDATION

- Company has to make the proper policy for the quality management.
- Company makes to proper team for the agile manufacturing system implementation.
- Fixed the lunch time (if possible)
- Prepare the work schedule and proper production planning for the shortage of raw materials
- Prepare a check sheet for the regular maintenance work

³Department of Mechanical Engineering, MSBTE, Pune, Maharashtra India

Abstract: The objective of this research was to find out whether using a specially developed isometric template helps students to reduce time and efforts while drawing isometric drawings. The standard method of comparison of performance of two groups has been used to achieve the objective. An Isometric template specially designed was given to a group of 15 students. The time measurement has been done on group using stopwatch performed by volunteers. It has been found that the group using the template shown average reduction in time of about 3.39 min. This time reduction is very much of importance at the time of examination. There has been no such kind of effort has been carried out for the objective stated above. The application of this tool may be useful for the students of technical education such as ITI, Diploma, and Engineering etc. The template can be improved by adding various other features like circles of various diameters, French curve, a roller etc. such that it can be useful for other drawing concepts.

Keywords: Isometric drawing; Engineering graphics; Isometric template; Technical drawing.

1. INTRODUCTION

The concept of an Isometric had existed in a rough empirical form for centuries. From the middle of the 19th century isometrics became an invaluable tool for engineers, and soon thereafter axonometric and isometric were incorporated in the curriculum of architectural training courses. According to Jan Krikke, "axonometric originated in China. Its function in Chinese art was similar to linear perspective in European art. Axonometry, and the pictorial grammar that goes with it, has taken on a new significance with the advent of visual computing" An isometric drawing is one of the most used drawings in engineering education. It also has a reputation of one of the most difficult to understand and draw. However the basic principal behind its inclusion in engineering curriculum worldwide is to develop imagination power of the students. It basically contains of three axonometric drawings and they are matched or imagined in such a way that they create a parallel projection technique. In Isometric drawings, the image plane is associated with the three principal axes which make equal angles. The three principal axes as shown in the Figure 1 are inclined at 120° and also parallel to the cube edges in the Isometric view. These three principal axes are known as isometric axes. There are two receding axes which are inclined at 30° to the horizontal line while the vertical axis is at 90° to the horizontal line. There are three planes called as isometric planes or isoplanes which contains the three visible faces of the cube. The lines from object which are parallel to the isometric axes are referred to as isometric lines whereas non parallel lines are known as non-isometric lines.

Fig. 1. Isometric axes in image plane

Fig. 2 a) Regular b) Reverse isometric

c) long-axis isometric

1.1 Importance of Isometric Drawing

Interpretation of the shape of an object from a multiview orthographic drawing requires a thorough knowledge of the principles of orthographic projections. A pictorial projection in general and an isometric projection in particular, helps the students and also the shop floor workers (from whom the knowledge of orthographic projection is not expected) to visualize clearly and fully the shape of the object. Pictorial drawings are mainly used to show complicated structures such as aircraft, rocket cell etc. Pictorial drawings in the form of exploded views are used in maintenance catalogues and manuals.

1.2 Types of Isometric Drawings

Different isometric views of an object can be obtained by positioning Isometric axes.

Three basic views are

1. Regular isometric,
 2. Reverse isometric
- And

3. Long-axis isometric as Shown in Figure 2.

In regular isometric, the viewer is looking from top down position so that the top of the object is seen. Whereas reverse isometric is exactly opposite to this view, Long axis is some kind of different view which is not generally used to describe the object.

1.3 Isometric Template

The Isometric template used in this research was apparently influenced by the Iso-sketch tool innovated by The Drawing Tool Company [4] [5] as shown in Figure 3a) & 3b). The template design is shown in Figure 2. It is consisting of various portions which are generally required to draw an isometric drawing. The template used in this particular research is as shown in Figure 3c) is having 30° lines from horizontal, The template was also designed by considering ergonomics of age group who are using it. The plastic material was used for it due to its various advantages over other materials. Figure 5 represents the actual prototype of the isometric template used by the group of students in this research.

Fig. 3 b) Isometric Template

Fig 3 c) Newly designed Isometric Template

2. RESEARCH METHODOLOGY

A group of 30 students [15 test candidates- 15 Volunteers] from First year of engineering class have contributed for the study first an isometric problem as shown in Figure 4 was discussed and taught to the all students appearing for the

test. The test candidates are then said to solve the problem again on a blank sheet. The 15 student volunteers out of 30 were asked to record the time required for solving the problem with simple drawing tools, and with using isometric template. They were first instructed how to use this tool/ template. And also the time required for the

drawing was calculated by volunteers. The data found is tabulated in Table1. A comparison was made and the results were plotted graphically as shown in Figure 6.

TABLE 1: comparison of time in min required for regular method and by using isometric template

Student Roll No.	Regular Method	Using Isometric template	Decrease in time reqd in min
1	12	8.21	3.79
2	11	7.53	3.47
3	12.21	8.3	3.91
4	13	9	4
5	13.11	9.14	3.97
6	9.55	6.56	2.99
7	15	9.45	5.55
8	14.48	9.52	4.96
9	11	8.14	2.86
10	11.09	7.3	3.79
11	11.37	8	3.37
12	10.1	9.36	0.74
13	10.53	9.4	1.13
14	16.46	13.11	3.35
15	17.1	14	3.1

Fig 5 Prototype of Isometric Template

Fig. 6. graphical representations of data from Table.no 1

2.1 The Data Found Out Was As Follows.

The average time reduction while drawing an isometric drawing using an Isometric tool has been show in Table 2. This clearly shows that there is significant reduction in time of about 3.39 min if student uses an Isometric template. Figure 7 represents the graphical plotting of these results.

TABLE 2 Average time reduction to draw Isomteric drawing using Isometric template

	Regular Method	Using Isometric template
Students appeared	15	15
Average time required to solve question in min.	12.53333 Min.	9.134667 Min.
Avg. time reduced to draw isometric using iso template tool	3.398667 Minutes	

Fig. 4. Isometric Problem Discussed

Fig. 7. Graphical representations of data from Table 2

3. CONCLUSION

Results of the tests carried out shown an encouraging

decrease in the time required to solve an isometric problem i.e. about 3.39 min. Hence it is found that using isometric template to solve a problem might help the students in exam so that their performance gets increased.

Development and Validation of Safety Climate Questionnaire for Manufacturing Industry in India

Bobby¹, Satnam Singh², Bhavneet Singh³

^{1,3}Department of Mechanical Engineering, Anand College of Engineering & Management, Kapurthala, Punjab, India

²Department of Mechanical Engineering, Lovely Professional University, Phagwara, Punjab, India

Abstract: The objective of this paper is to develop and validate a safety climate questionnaire or safety related perception of workers to study the safety and health conditions in small and medium scale industries in Punjab. Safety is big concern for organizations because it leads to many direct and indirect costs. Safety climate is the employee's perceptions of policies, procedures, and practices regarding safety in an organization. The purpose of this study is to develop and explore the content and face validity and internal consistency of the safety climate questionnaire for manufacturing sector in India. The questionnaire is developed through literature review and discussions with experts. Panel of seven experts who consist of safety officers, professionals have vast experience of manufacturing sector in India. Content validity was measured by content validity index (CVI) and a modified kappa index. A pilot study was conducted to test the internal consistency of the questionnaire by calculating Cronbach's alpha. Thirty out of forty-five items showed excellent content validity, six items showed good content validity, eight items showed fair content validity, and one item showed poor content validity. The average content validity of the questionnaire was .80 and ranged from .79 to .92 for the six subscales. The face validity was good with no major remarks were given. We conclude that questionnaire showed good content validity and this questionnaire seems to be an acceptable tool to evaluate safety climate.

Keywords: Safety climate, Content validity index, Modified kappa index, Cronbach's alpha

1. INTRODUCTION

The Bhopal gas tragedy that occurred in India was an eye opener for industry in India. Investigation and studies of this incident revealed the lack of seriousness of human life by company management, ignorance and complacency of workers and totally irresponsible attitude from regulatory agencies (Gupta, 2002). Learning lessons from this incident and realizing the large compensatory expenses, production losses, and loss of confidence of workers, company managements in India have shown interest to invest for safety infrastructure in all types of industries, especially, major accident hazard industries (ILO, 1996).

Even after two decades since the Bhopal disaster, the fatal accident rate in Indian manufacturing sector stay close to 20 fatalities per hundred thousand employees against 1-6 in advanced countries (DGFALSI, 2006). According to the data of DGFALSI there are around 1383 fatal and 28441 non fatal injuries occurred in India in 2012. In India the management of occupational safety and health of workers at organizational level is governed by The Factories Act, 1948 (Central Act 63 of 1948) and rules formed there under by the state governments. Recently there has been a movement away from safety measures purely based on retrospective data or "lagging indicators" such as lost time accident rates and incidents towards so called "leading indicators" such as safety audits or measurement of safety climate (Flin et al., 2000; Mohamed, 2002).

1.1 Safety climate

Safety climate can defined as employees shared perceptions of safety policies, procedures, practices as well as overall importance and the true priority of safety at work (Griffin and Neal, 2000; Zohar, 1980). It is multidimensional factor. Safety climate was considered to be a part of organizational climate and reflected the employee's attitude and perceptions at a particular time and at a particular place (Schneider and Gunnarson, 1991; Cox and Flin, 1998; HSE, 1999). Safety climate provides a snapshot of an organizations "state of safety" at a discrete point in time (Cheyne et al., 1998; Huang et al., 2007).

Zohar (1980) developed the first measure of safety climate, using a 40 item questionnaire covering the metal fabrication, textiles and food processing industries. After factor analysis his model included eight factors with workers perceptions of the importance of safety training, management attitude towards safety, effects of safe conducts on promotion, level of risk, work pace, status of safety officer, effects of safe conducts on social status and status of safety committee. Brown and Holmes tried to replicate this structure in America and found that it was not supported. They arrived at new set of three factors. Hale (2000) noted that few safety climate have been reused between studies and that whenever this has occurred, factor structures and results have not usually been replicated.

In recent decades, it has been well documented that safety climate is related to safety behavior and unintentional injuries in workplaces in western countries. A recent meta-analytic review revealed that safety climate offer robust predictions of the occurrence of occupational injuries and better self reported safety behavior across industries (Clarke, 2000a). Moreover, it was found that a positive safety climate can encourage safe performance either through rewards or through principles of social exchange (Zohar, 2000; Clarke, 2006). A number of studies showed that safety climate was associated with safety behavior and lower workplace accident rates (Griffin and Neal, 2000; Zohar, 2000; Sin et al., 2004; Smith et al., 2006; Clarke, 2006; Zohar et al., 2014). As to the safety climate in manufacturing enterprises, there were a lot of investigation reports in many countries. Zohar (2000) found that safety climate predicted micro accidents records at a manufacturing plant.

Many studies have investigated the construct of safety climate in organizations. However, they have not reached to a common agreement on safety climate dimensions. The review of previous studies showed that management commitment to safety is a common dimension for safety climate. Seo et al. indicated that safety climate dimensions can be categorized into five themes: management commitment to safety, supervisor safety support, employee participation, and competence level of employee about safety. A review of 18 safety climate surveys by Flin et al. revealed that safety system, management, risk, work procedure, and competence were the most frequent dimensions. Flin et al. also identified work pressure as another frequently used dimension. Safety communication, safety training, work environment, safety information were found as other dimensions of safety climate.

There are several methods to assess the validity of a questionnaire. The content validity of a questionnaire can be examined in development and judgment stages. The development stage is usually carried out through performing a literature review or conducting interviews with focus groups. The quantitative analysis of the content validity is determined by application of statistical methods. The content validity index (CVI) is one of the methods to find out the validity of a questionnaire.

To the authors' knowledge, this study is the first one to develop and to validate a safety climate questionnaire for manufacturing industry in India. Because of unique nature of safety climate in countries, industries, companies, and even different sector of organization, we found a need to develop a new questionnaire to examine safety climate in Indian manufacturing industry. In this study, we developed a new safety climate questionnaire and also examine its validity.

2. METHOD

2.1 Development of questionnaire

A literature review conducted and a total of 345 safety climate items generated from the available questionnaire in the published articles and the documents. The number of items reduced to 46 after discussing with experts related to manufacturing industry. We identified five dimensions of the safety climate and those dimensions are management commitment, safety training, safety communication, safety knowledge and compliance, work pressure.

2.2 Experts' agreement on item relevance

The questionnaire was tested for content validity (Lynn, 1986; Pilot et al., 2000). Each of the experts was asked to rate each questionnaire item on its relevance using a 4-point Likert-type format, ranging from "highly relevant" (score 4), "quite relevant" (score 3), "somewhat relevant" (score 2), to "not relevant" (score 1). In addition, experts were asked to indicate whether an item's wording should be revised. If the expert recommended revision, he/she was encouraged to revise the item.

An item content validity index (I-CVI) was calculated for each item. For the total questionnaire and each scale, a scale content validity index (S-CVI) was calculated. There are two methods for calculating content validity of whole scale or questionnaire. The first method is the universal agreement method as proportion of items that achieved a rating of 3 or 4 by all experts. The second method was to calculate the average of all the I-CVIs of the individual items (S-CVI Ave). Content validity indexes were rated as good when I-CVI, S-CVI Ave and S-CVI UA were at least 0.78, 0.90, and 0.80, respectively (Pilot et al., 2000). The I-CVI is the proportion of experts who rate its content as valid (a relevance rating of 3 or 4) (Lynn, 1986; Pilot et al., 2000). To calculate a S-CVI, different methods were tested (Pilot et al. 2000). The first method was to require 'universal agreement' among experts, defining the S-CVI as the proportion of items on an instrument that achieved a rating of 3 or 4 by all the experts (S-CVIUA). The second method was to calculate the average of all the I-CVIs of the individual items (S-CVI Ave). Content validity indexes were rated as good when I-CVI, S-CVI Ave and S-CVIUA were at least 0.78, 0.90, and 0.80, respectively (Pilot et al., 2000).

To counter the limitations of the CVI, an I-CVI was computed correcting for chance agreement by calculating modified kappa statistic (k^*), which is the index of arrangement among experts that the item is relevant (Pilot et al., 2007). To compute the modified kappa, first we have to calculate probability of chance agreement: $P_c = [N! / (N-A)!] * 0.5^N$ where N is the number of experts and A is the number of experts give rating 3 or 4. k^* was calculated with formula $k^* = [I-CVI - P_c] / [1 - P_c]$ (Pilot et al.,

2007). Finally standard values described in Flies (1981) and Cicchetti and Sparrow (1981) were applied to evaluate whether the K value was fair, good, excellent.

2.3 Face validity

The face validity was tested by 5 experts who have the knowledge and experience about worker's safety in

manufacturing industry in India. They studied the questionnaire and were guided by questions such as: "Are these questions understandable and clear? If 'no' please indicate the item and feel free to propose a better formulation." Comments were then discussed by the researchers.

S. No	Management commitment	Total no. of Experts	Number of experts give rating 3 or 4	I-CVI	Pc	K*
1	My company responds quickly to safety concerns	7	7	1	0	1
2	My company provides safety information	7	7	1	0	1

3	I know how to use safety equipments and standard work procedures	7	4	0.57	0.273	0.4
4	I carry out my work in a safe manner	7	3	0.42	0.273	0.2
5	I know how to reduce the risk of accidents and incidents in the workplace	7	7	1	0	1
6	I know what are the hazards associated with my job and the necessary precautions to be taken while doing my job	7	7	1	0	1
7	Use a tool to adjust a dangerous part of a machine	7	6	0.85	0.054	0.84
	Work Pressure					
1	I believe there is sometimes pressure to put production before safety	7	7	1	0	1
2	Rules relating to personal safety sometimes make it difficult to keep with production target	7	7	1		1
3	My health has been negatively affected by my work	7	5	0.71	0.164	0.65
4	We're just running around all the time from one job to another, not completing them properly	4	4	0.57	0.273	0.4
5	I have unachievable deadlines	7	6	0.85	0.054	0.84
6	I have to work very intensively	7	6	0.85	0.054	0.84
7	I have to neglect some tasks because I have too much to do	7	7	1	0	1
8	I am unable to take sufficient breaks	7	5	0.71	0.164	0.65

The 'bold and underline values 'shows an item with content validity index below 0.78.

I-CVI (item content validity index) = number giving a rating of 3 or 4/number of experts.

Pc (probability of a chance occurrence) = $[N!/A!(N-A)!] \cdot 0.5^N$ where N = number of experts and A = number agreeing on good relevance.

K* = kappa designating agreement on relevance: $k^* = (I-CVI - pc)/(1 - pc)$.

Evaluation criteria for kappa: fair = k of 0.40–0.59; good = k of 0.60–0.74; and excellent = k > 0.74.

S-CVI Ave (average scale content validity index) = mean of I-CVI

3. RESULTS

3.1 Validation of questionnaire based on experts' agreement

Seven experts evaluated the questionnaire out of which all had more than five years of experience in manufacturing

industry. Thirty five out of forty five (78%) questionnaire items showed excellent content validity ($I-CVI \geq 0.78$ and $K^* > 0.74$), six items (13%) showed good content validity ($I-CVI < 0.78$ and $0.60 \leq K^* \leq 0.74$), four items (9%) was considered as fair ($I-CVI < 0.78$ and $0.40 \leq K^* \leq 0.59$), one item considered poor and invalid ($I-CVI < 0.78$ and $K^* \leq 0.4$). The scale content validity for the questionnaire was 1.26, indicating that the amount of items with unanimity among experts was low. The average scale content validity (S-CVI Ave) was 0.71 below the cut off 0.90.

S-CVI Ave. and S-CVI UA for the management commitment were 0.88 and 0.54, for safety training 0.83 and 0.37, for safety communication 0.91 and 0.4, for safety knowledge and compliance 0.83 and 0.57, and for work pressure 0.83 and 0.37.

A Study of Power Sector - Safety Issues & Indian Scenario

Chandan Krishna Mukherjee

Department of Mechanical Engineering, SSBT's College of Engineering and Technology Jalgaon, Maharashtra, India

Abstract: Power sector plays a major role in the industrial & economic development of a country. In India it is increasing by more than 5.5 % annually, thermal power plants accounting for more than 85 % of the utility power generated . Concern for depleting fossil fuel reserves, pollution & safety related issues has compelled the power ministry to reframe its power generation policy including development of power plants based on renewable energy sources (RES) . In this paper, different sources of energy used for power generation, related safety issues, the current Indian scenario & government policy pertaining thereto have been discussed.

Keywords: Thermal, Nuclear, Hydel & other RES based power plants

1. POWER SECTOR & RELATED SAFETY ISSUES

Electricity is essential for industrial development, economic growth and improving living condition of people . The power sector thus plays a very important role in society . Power generation involves conversion of an available form of energy using an appropriate method . Compared to thermal / nuclear power plants, RES based power plants have low operating & maintenance cost, do not emit any pollutants or pose any serious health hazard or cause depletion of our fossil fuel reserves . The various sub types of RES are discussed below :-

Solar based power plant - Solar power plants are considered as the safest, cleanest, cheapest & most eco friendly method for generating power. These are particularly suitable for areas having predominantly hot, dry & sunny weather. Depending upon the method of conversion of solar energy into electric, these are of 2 types. a) Solar Thermal power plants – The sunlight is collected & concentrated using parabolic mirrors / lenses to heat water & produce the high temperature steam required for power generation, even long after sun set. This is less popular because of requirement of considerable water, water treatment, scaling & corrosion problems, comparatively higher installation, operating & maintenance cost. b) Photo-Voltaic power plants –Here, numerous solar panels (composed of interconnected photo-voltaic cells) are set up on a strip of infertile / unproductive land (called solar farm). When exposed to sun light, these solar panels generate electricity. Smaller solar panels can be installed on building rooftops / light posts for household & street light electrification. The power generated during daytime has to be stored in batteries for consumption after sunset. Solar panels & batteries are not prohibitively expensive, installation, operating & maintenance cost is low. With the

advent of thin polycrystalline solar panels at much cheaper rates, PV solar plants are becoming increasingly popular.

Wind based Power Plant - This is suitable for places regularly experiencing high wind velocities. A wind farm consists of several wind turbines being placed in a zig-zag array ; the spacing being 5 – 9 times rotor diameter across the prominent wind direction and 3 – 5 times rotor diameter along the prominent wind direction. Higher the height of the rotor hub above ground (usually 100 – 120 m), higher the wind velocity & greater the power generating capacity. The initial equipment & setup cost is substantially high but operating & maintenance cost is low & land requirement is < 1 acre / MW, The in – between space can be used for cultivation, cattle grazing or setting up solar panels as in Solar – Wind hybrid power plant.

Biomass based power plant - Biomass is organic matter obtained from living / dead organisms eg. cow dung, rice husks, crop stalks, agro residue etc., which is abundantly produced in rural areas. If burnt or left to decay, it would emit green house gasses & cause pollution. Alternatively it can be beneficially utilized as a fuel source (as biomass or biogas) not only for domestic cooking but also in small thermal power plants, to produce steam for power generation for village electrification & agro / allied industries (sugar, brewery, rice mill, paper, textile, fertilizer, etc.).

Geothermal based Power Plant - In the vicinity of volcanic activities / hot springs, underground water is usually available at high temperature & pressure. Using deep drilling & extraction technology, this water is pumped to the surface in steam form & used to rotate a turbine for generating electricity. The underground water temperature should be > 180 °C in flash steam type, > 150 °C in dry steam type or even > 60 °C in binary cycle type power

plant. In the first 2 types, a mixture of gasses like CO₂, CH₄, NH₃, H₂S are released as air pollutants but in quantities much less compared to thermal power plants. Exploration & drilling cost is high, the thermal efficiency is low (only 7 - 10 %) but operational costs are quite low.

Tidal water based Power Plant - In coastal areas, the difference in water level heights during high tide & low tide creates tidal waves which periodically lash the sea shore with considerable energy. This energy is used to rotate a turbine & generate electricity. For the project to be feasible, the average height of the tidal waves should be significantly large, the project site should not adversely interfere with marine life / fishing / naval activities. They are susceptible to damage by tsunami & hurricane & power generation fluctuates with the tide but operation & maintenance costs are low.

Hydro-electric (Hydel) Power Plants - A dam is built across a fast flowing perennial river to form a reservoir on the upstream side. Controlled release of water from the reservoir via a penstock is used to rotate a turbine (mostly Francis type) & generate electricity. Hydroelectric power plants also *help in irrigation, flood control* & do not cause pollution but are not 100 % eco – friendly. During construction, a huge land area on the upstream side gets inundated & the vegetation therein decays, releasing a huge amount of green house gasses like CO₂ & CH₄. Also people residing along those parts (mostly tribal villagers) have to be relocated & rehabilitated. Water flow on the downstream side is greatly reduced, adversely affecting the livelihood of farmers / fishermen of those areas & often leading to water disputes between neighbouring states / countries. Hydroelectric power plants can cause disastrous floods on the downstream side, resulting in huge damage to government property, immense hardship & unquantifiable personal loss to families residing in the inundation zone. This may be due to emergency water release or dam failure caused by natural calamities like earthquake, flash flood, land slide etc. or man – made causes like terror attacks, improper dam construction, inadequate repair of old dams, malfunction of sluice gate operating system, human error in timing & rate of release of excess water Jain R.K, 2011; Sharma, 2013.. During dam design, due consideration should be given to foundation geology, seismic activities, susceptibility to landslides, average & maximum rainfall, permeability of dam material, provision for drainage of seepage water & adequate number of spillways. Proper rehabilitation schemes should be offered to the displaced tribals from upstream side in return for their co-operation. Construction / operational cost, water & power sharing during draught as well as excessive rainfall between upstream & downstream communities should be equitably finalized at project design stage to avoid subsequent disputes. Timing, duration & rate of release of excess water should be carefully calculated so as not to cause / aggravate

flood situation. Warning system should be installed & activated prior to release of water to prevent drowning of fishermen / bathers on downstream side. There should be a well designed & rehearsed emergency action plan (EAP) including inundation map for flood due to emergency water release / dam failure. People should not be allowed to swim, boat or fish in the reservoir within 500m of the inlet to the penstock. River dredging & dam repair should be undertaken periodically.

Nuclear Power Plants - When a minute quantity of fissile radioactive material (U²³⁵, U²³³, Pu²³⁹) is bombarded with fast moving neutron, its atom disintegrates into 2 lighter radioactive atoms (called fission fragments), releasing a huge amount of energy & ionization radiation. 2-3 fast moving neutrons are also emitted, causing further nuclear fission to occur in a chain reaction. In a nuclear power plant reactor, this nuclear fission is controlled using regulators (lead / graphite rods) to absorb neutrons & moderators (eg. light water, heavy water D₂O), to reduce the speed of fast neutrons - the heat released is used to produce superheated steam for power generation. Thermal efficiency > 40 % is attained due to higher steam temperature (> 600 °C). Fertile mineral Th²³² is available in comparatively greater quantity, which can absorb a neutron & convert to fissile U²³³. Natural uranium ore is scantily available, containing only about 0.7 % of fissile U²³⁵, remaining 99.3 % is fertile U²³⁸ which can absorb a neutron & convert to fissile Pu²³⁹. Very few countries have nuclear grade uranium deposits & constitute the NSG (Nuclear Suppliers Group). The mined uranium ore is concentrated by solvent extraction & ion exchange process, to obtain crude 70 – 90 % uranium concentrate in yellow cake form. This is calcinated to UO₃, hydrogenated to UO₂, passed through hydrogen fluoride & processed to obtain UF₆ gas. This is fed into the centrifuge in an enrichment plant where the heavier U²³⁸ migrates to the outer periphery & mixture containing 2 – 3 % of the lighter U²³⁵ is collected from the central core region. This enriched UF₆ gas is converted to uranium metal / UO₂ / uranium carbide salt, mixed with Th²³², converted into small cylindrical pellets, placed in stainless steel / Zirconium tubes & sealed. A reactor requires 100 – 300 fuel elements, each comprising of a cluster of 50 – 300 of these sealed tubes called fuel rods. A large amount of ionization radiation is emitted during the fission reaction, storage & handling of radioactive fuel material, recycling spent fuel material & disposal of nuclear wastes. These harmful radiations pose a major occupational health & environmental hazard. The International Commission on Radiological Protection (ICRP) recommends a max. occupational radiation exposure dose of 50 mSv / yr or a max. of 100 mSv in a consecutive five-year period. The radiation exposure dose is measured using a personal dosimeter & can be minimized by reducing exposure time, increasing distance from radiation source or by using a shield made of some radiation absorbing material like lead

or concrete. All personnel must be provided with protective clothing & adequately trained. The reactor is set up in a full containment facility having concrete / lead walls to prevent leakage of any stray radiation into the environment. This facility is however susceptible to damage by reactor explosion, earthquake or terrorist attacks and can cause extensive environmental disaster. Storage & disposal of radioactive nuclear waste in large quantity is an environmental hazard. The present practice is to mix it with concrete, pour it in steel drums & bury the sealed drums in abandoned mines or dump them in underwater ridges, more than 100 km from the shoreline. Fissile material can be used by terrorists to make nuclear bombs & so strict vigilance has to be maintained at fuel enrichment, fabrication & recycling facilities to prevent illegal smuggling Jain R.K, 2011; Rao 2012

Thermal Power Plants - These are large capital & labour intensive installations, spread over a vast land area, having high operational & maintenance costs. Based on Rankine cycle, super heated steam produced in a high pressure boiler (mostly water tube type eg. Babcock Wilcox) is allowed to expand adiabatically to rotate a turbine coupled to a generator for generating electricity. The boiler is fired by burning a fossil fuel (natural gas, diesel or coal) having high calorific value. Natural gas & crude oil are simultaneously discharged from on shore or off shore oil wells. Crude oil undergoes fractional distillation in an oil refinery to yield diesel, while natural gas is liquefied under high pressure for ease in transport. Coal has to be extracted from surface or underground mines & beneficiated in a coal washery at the pit head to reduce ash content & transport cost. Mining & processing a highly inflammable fossil fuel is very hazardous^[1]. Transporting it in bulk quantity over considerable distance to the power plant & storing it there is equally hazardous. Feeding coal into the furnace, removing & disposing huge quantity of ash there from requires special equipment & adequate precautionary measures. Boiler operation & maintenance requires specialized personnel & special precautions. Boiler feed water must enter via a water treatment plant to minimize scaling & corrosion problems. Boiler walls / tubes must be periodically cleaned, inspected & repaired. Thermal power plants emit a huge amount of green house gases (mainly CO₂, SO₂, NO_x) as well as a huge amount of suspended particulate matter (SPM - mainly fly ash & unburned carbon particles) which is a serious health hazard for all residents within a 5 km radius & harmful for the environment. So coal beneficiation, installation of dust collector & more efficient boilers is essential.

Power transmission & distribution - The power generated in various power plants are transmitted via high voltage (132 KV) transmission lines over long distances to a central grid for load wise distribution to the numerous consumers

via an intricate network of distribution lines & substations where the voltage is sequentially reduced. Transmission lines generate strong & harmful electromagnetic fields. So these should not pass through residential areas & should be located high above the ground. The power lines may break by uprooted trees during cyclones. Hence there should be strategically located automatic circuit breakers to prevent electrocution & short circuit. Linesmen should be well trained & provided with harness. The supporting towers are susceptible to lightning strikes & should be well grounded. Power thefts increase power cost for consumer, often result in fire due to short circuit / death due to electric shock & hence needs to be curbed. The high capacity step up & step down transformers contain transformer oil having a high flash point > 140 °C but can catch fire, so fire prevention & protection measures should be adequate. Small transformers set up in different parts of the cities & towns should be placed high above ground & well fenced with danger signboards to prevent unauthorized entry./ accidents.

2. THE CURRENT INDIAN SCENARIO

Power generated in different states are interconnected to form 5 regional grids – Eastern, North Eastern, Northern, Western & Southern. These grids have been synchronously interconnected in phases, in the period 1991 - 2013, to form a National grid, which is monitored & coordinated by Central Electricity Authority (CEA). Power transmission / distribution losses & power theft constitutes more than 20 % of power generated & is a cause for concern. As on 31/12/1947, India had coal based thermal power plant of 756 MW capacity, diesel based thermal power plant of 98 MW & hydroelectric power plant of 508 MW - a total installed capacity of 1362 MW only. As on 30/6/2017 the captive power generating capacity is 50289 MW & the utility power generating capacity (thermal, nuclear & large hydro) is 329231 MW, the type-wise distribution being given in Tab.1.

Coal based thermal power plants account for almost 60 % of the installed capacity for utility power, more than 85 % of utility power generation & roughly 72 % of the domestic coal consumption. Natural gas & crude oil are rarely used, mostly in captive power plants. Of the captive power plants installed, 28.4 % are diesel based & 12 % are gas based. Large plants are mostly operated by government undertakings like National Thermal Power Corporation (NTPC), North East Electric Power Corporation (NEEPCO) & Damodar Valley Corporation (DVC). The major thermal power plants are - Vindhyachal thermal power plant (6 x 210 MW, 6 x 500 MW) in Singrauli, Madhya Pradesh, Mundra thermal power plant (4 x 330 MW, 5 x 660 MW) & Mundra ultra mega (5 x 800 MW) power plant in Kutch, Gujarat, Talcher super thermal power plant (6 x 500 MW) in Odisha & Sipat super thermal power plant (3 x 500 MW, 3 x 660 MW) in Bilaspur, Chattisgarh.

TABLE 1: India's utility power generating capacity & Generation

Power Plant type based on Fuel used	As % of total Installed Capacity as on 30/6/2017	Generation in 2016-17 (Target for 2017-18) (1 BU = 1000 GWh)
Coal based –	59.1 %	944.9 BU
Gas based–	7.6 %	49.1 BU
Oil based–	0.3 %	0.3 BU
Total Thermal Power Plant	67.0 %	994.3 BU (1042)
Nuclear Power Plants	2.1 %	37.9 BU (41)
Large Hydro-electric Power Plant	13.6 %	122.3 BU (141.4)
Wind based –	9.8 %	46.0 BU
Solar based power plant –	3.7 %	12.1 BU
Biogas based –	2.5 %	Na
Small hydro based –	1.3 %	Na
Urban / Industrial waste based -	0.3 %	Na
Total Renewable energy source based power plant	17.6 %	58.1 BU

Hydel plants have an installed capacity of almost 50 GW, 92 % of which are large & operated by government undertakings like National Hydroelectric Power Corporation (NHPC), NEEPCO, DVC, Sutlej Jal Vidyut Nigam Ltd. (SJVNL), Tehri Hydro Development Corporation (THDC), Bhakra Beas Management Board (BBMB) & NTPC – Hydro. The major hydel plants are - 2400 MW Tehri dam on Bhagirathi river in Uttarakhand, 1960 MW Koyna dam on Koyna river in Satara, Maharashtra, 1670 MW Srisailem dam on Krishna river in Andhra Pradesh, 1500 MW Nathpa Jhakri dam on Sutlej river in Himachal Pradesh, 1450 MW Sardar Sarovar dam on Narmada river in Navagam, Gujarat, 1325 MW Bhakra Nangal dam on Sutlej river in Bilaspur, Himachal Pradesh.

Nuclear power plants in India are exclusively owned by the Central Govt., under administrative control of Dept. of Atomic Energy & operated by Nuclear Power Corporation Ltd. (NPCL). Uranium is imported from Russia, Mongolia, Kazakhstan, Namibia & Argentina. India has 22 units, mostly of PHWR (pressurized heavy water reactor) type, of 6.78 GW installed capacity at Rawatbhata in Rajasthan, Narora in Uttar Pradesh, Kakrapar in Gujarat, Kaiga in Karnataka, Tarapur & Jaitapur in Maharashtra, Kalpakkam & Kudankulam in Tamil Nadu.

Small hydro electric power plants & other RES (wind, solar, biomass, tidal, geothermal) based power plants are mostly privately owned small units under the control of Ministry of New & Renewable Energy (MNRE). National Institute of Wind Energy (NIWE) has helped in promoting wind based power plants in the last couple of years. Several wind farms have been set up in Rajasthan, Karnataka, Madhya Pradesh as well as along the coastal region of Tamil Nadu, Maharashtra, Gujarat, Andhra Pradesh & Kerala ; the total installed capacity is about 32 GW. Due to

the Southwest monsoon, 70 % of the generation occurs during June – November. The major wind power plants are - the 1500 MW Muppandal wind farm at Kanyakumari, Tamil Nadu ; 1064 MW Suzlon wind farm at Jaisalmer, Rajasthan ; and 528 MW Parakh wind farm at Dhule, Maharashtra. Solar power plants are becoming increasingly popular in numerous areas of Rajasthan, Andhra Pradesh, Tamil Nadu, Telengana, Gujarat, Karnataka & Maharashtra. The major PV solar plants are – 648 MW Kamuthi plant in Madurai, Tamil Nadu, 221 MW Charanka plant in Patan, Gujarat, 151 MW Welspun plant in Neemuch, Madhya Pradesh, 148 MW ReNew plant in Nizamabad, Telengana & 125 MW Sakri plant in Dhule, Maharashtra. The major solar thermal power plants are - 100 MW Dhursar plant, 50 MW Godawari plant (both in Jaisalmer, Rajasthan), 50 MW Megha plant in Anantpur. In the NTPC – Dadri thermal power plant at Ghaziabad, Uttar Pradesh, a solar heat exchanger has been installed in parallel with the high pressure coal fired boiler no. 6. Government is actively promoting biomass based power plants for village electrification. The 20 MW biomass power plant in Sirohi, Rajasthan is the largest of its kind.

3. GOVERNMENT POLICY & PLAN

Reducing power losses & theft is of top priority. India is concerned about depleting fossil fuel reserves, increasing air pollution & global warming. Under pressure from international environmental agencies, our government is committed to reduce its carbon footprint, lower its emission of green house gasses & reduce its dependence on thermal power plants by 2020. Indian coal is mostly of inferior grade (avg. gross calorific value is 4500 Kcal / kg, low carbon, high ash & sulphur content). So emission of green house gasses & coal consumption (0.7 kg / kWh) is much higher compared to USA, Australia or other EU countries.

As per guidelines by Ministry of Environment & Forests coal having ash content < 34 % is to be used. Coal washeries are being setup at the coal mine pithead, on own & operate basis. Old plants are being modernized with capacity increase from 60 – 220 MW to 600 – 800 MW, to improve efficiency, reduce pollutant emissions & power generation cost. Several large hydel projects having an installed capacity of about 14 GW are under construction. Rich reserves of good grade Uranium have been discovered in Tummalapalla belt & Bhima basin of Karnataka & existing nuclear plants are to be expanded by additional 11 units of 13.2 GW capacity. The Ganga delta in Sunderbans, Gulf of Khambat & Gulf of Kutch in Gujarat, are having average tidal wave heights of 2.97 m, 6.77 m & 5.23 m respectively due to variations in local topography like shelving, funneling etc. & are prospective tidal power plant sites. A 3.75 MW Durgaduani mini power plant project in the Sunderbans is currently under construction. A geothermal power plant of 2 MW is under construction in Puga, J & K. Other prospective sites are Chhumathang in J & K, Tattapani in Chhattisgarh, Cambay Graben in Gujarat, Manikaran in Himachal Pradesh & Surajkund in Jharkhand. Government is actively sponsoring & promoting RES projects for rural electrification / captive use. Domestic power consumption is being reduced by popularizing solar appliances.

4. CONCLUSION

The different types of power plants, related hazards & safety counter measures, current Indian scenario, including government policy & plans have been discussed. It is hoped that the information presented in this paper will be useful to the decision makers in the industry & particularly to those engineering students who are interested in joining this industry.

Implementation Investigation of Factors for Enhancement in Productivity with Economic Conclusions

Sunil Kumar, Toshit Jain, Manish Rawat

Department of Mechanical Engineering, GLA University, Mathura, Uttar Pradesh, India

Abstract: Productivity is of concern rather an extremely important concern for any manufacturing industry. Several ways of improving productivity are suggested in this paper. Paper explains various productivity parameters which improved in various sections of Industry under consideration. Areas of weak productivity identified which indulges heavy set up or operational cost identified and this paper suggests alternate ways of doing the same process which resulted in cost saving. Cost saving directly means increase in profit. This paper gives the details of all such processes which reflect in cost saving of company undertaken as case study.

Keywords: Productivity, Energy saving, Machining, Machine Shop, Cost Saving

1. INTRODUCTION

Productivity usually defined as a ratio between output and input. It is a fundamental concept considering this efficient and effective use of resources. Dealing with continuous competition, company not only needs to produce quality products but excellence production systems and management also plays an important roles. . The aim of study is to improve the productivity in manufacturing industry. The objective is to identify the defect of the company and create a better solution to improve performance. Various industrial engineering technique and tools is implementing in this study in order to investigate and solve the problem that occurs in the production.

1.1. Objectives of selecting parameters

- 1) Implementation of tools from industrial engineering in manufacturing industry.
- 2) Identification of defects in high frequency at workstations
- 3) Introduction of latest methods in same manufacturing firm.
- 4) Improvement of productivity in firm.

2. LITERATURE SURVEY

Piotr Tomaszews et al., 2006 identified and analyze the impact comparative productivity of given two projects. One represented an initial development stage while the other represents a subsequent and thus more matured development stage. Henri Juslen et al., 2007 examined whether or not a controllable task-lighting system that allowed people to select high lighting levels will enhance

productivity under real working conditions. Hannu Rantanen, 2001 found that internal obstacles form the only category of obstacles which is clearly under the control of the firm. **Carrino et al., 2007** studies the characteristic complications of GMAW processes, owing above to the large count of main variable values and to their inter-dependency, proposed all possible results by designing a fuzzy-logic-based scheme, where elements were dogged by preparing an artificial neural network (ANN).

Dimitrov et al. focus is put on the effectual utilization of 5-axis machining with the high-end CAD/CAM-systems for their tenacity of productivity and quality up gradation. The analysis of several case studies like their comparison between 3-axis machining and 5-axis cutting as a substitute possibility has been proposed.

Weston paper accounts on progresses that assurance such a step change, primarily in auto, aero and construction equipment industries with roll out to other subdivisions. It labels how integrated people, product, process and plant (ip4) virtual environments and innovative forms.

2.1 Company Analysis

As per the consolidated - Audited financial statement in the fiscal year of 2012, total overall operating revenue in the firm increased by 10.8%, from Indian Rupees 2, 739.07 tens of millions to Indian Rupees 3, 039.68 tens of millions. So that the operating results increases from Indian Rupees 166.4 tens of millions to Indian Rupees 194.11 tens of millions which got at 16.65% change in overall. Returns on its equity (Net income/Total equity) move up to 14.25% to 14.72%, the Return On Asset (Net income / Total Asset) moved from 3.64% to 4.07% and the Net Margin in Profit

(Net Income/Net Sales) went from 2.94% to 3.14% when measure up to to the same phase of last year. The Debt against Equity Ratio was 262.38% to 293.13% of last year.

Fig. 1. Company Process layout

3. PRODUCTIVITY ANALYSIS:

3.1. Material Productivity: It is nothing but ratio between output and material input. Material Productivity becomes a key factor in economic production as given by:

$$\text{Material Productivity} = \frac{\text{Output}}{\text{Total material used as input}}$$

3.2. Labour Productivity: It is the ratio of output to human input or it may also be defined as ratio of total revenue from production to expenditure on labour.

$$\text{Labour Productivity} = \frac{\text{Total Revenue from production}}{\text{Expenditure on labour}}$$

3.3. Capital Productivity: It is the ratio of Turnover to Capital input.

$$\text{Capital Productivity} = \frac{\text{Turnover}}{\text{Capital Input}}$$

3.4. Machine Productivity: It is the ratio of output and Actual machine hours used.

$$\text{Machine Productivity} = \frac{\text{Output}}{\text{Actual machine hrs. used}}$$

3.5. Overall Productivity: It is the ratio of total output to the total input i.e labour input, material input, capital input and machine input.

$$\text{Overall Productivity} = \frac{\text{Total Output}}{\text{labour input} + \text{material input} + \text{capital input} + \text{machine input}}$$

4. PROCESS ANALYSIS OF SELECTED JOBS:

Fig.2. Selected Areas

5. ANALYSIS OF VARIOUS PROCESSES IN DESIGN SHOP

5.1. Pressure Relief Valve (Sand witch Plate Design) Replaced with Line mounted

In old method pressure relief valve is used. The drawing of which is shown below:

Fig. 3. Pressure Relief Valve

Fig. 4. Line Mounted Pressure Relief Valve (Edosomwan, 1986)

5.1.1. New Process Description:

Line Mounted Pressure Relief valves are used.

1. Easy maintenance, high reliability.
2. Less cost.

5.1.2. Total Saving:

1. 25 Mechanical Presses
2. 05 Hydraulic Presses
3. Cost of line mounted valves including pipe fittings (2 nos.) = Rs 3550 + 450 = Rs 4000
4. Annual Savings = $(05 \times 16450) + (27 \times 6705) - (32 \times 4000) = \text{Rs } 135000$

5.2. Inbuilt Lubrication Tank In Bottom Heads

In old method “separate lubrication tank” was used which was placed on ground. The drawing of which is shown below:

Fig. 5. Press showing separate lubrication tank

Fig. 6. Press showing inbuilt lubrication tank

5.2.1. New Process Description

1. Subject job did not have MB and Die cushion. So we have designed the lubrication tank inbuilt in bed fabrication.
2. We saved the separate fabricated tank.
3. Reduction in piping.

5.2.2. Total Saving:

1. Oil tank fabrication saved. (Rs. 70 per kg. for 725 kg weight of oil tank).
2. Net Savings = Rs 57750- 16800=40950 per press.
8Taking 2 presses annually, Total savings = Rs. 81900

5.3. Flange (Drive Shaft Assembly) Is Fabricated.

Fig. 7. Old Flange

Fig. 8. New Flange

5.3.1. New Process Description:

1. Flange is machined from a fabrication.
2. Machining reduced to a great extent.
3. Fewer Raw Materials required.

5.3.2. New Cost Analysis:

1. Subcontracting Cost = Rs 3700 / piece
2. Subcontracting Machining Cost = Rs 1200 /piece
3. Subcontracting Material& Fabrication Cost = Rs 2460/pc
4. Total Subcontracting Cost = Rs 3660 /piece

5.3.3. Total Savings:

Annually (considering 25 presses annually) = Rs 6000- 3660
= $2340 \times 25 = \text{Rs } 58500$

5.4. Changes in Manufacturing Process Of Mechanical Press

Fig. 9. Old Housing

5.4.1 New Method Description

Fig. 10: New Housing

Now housing is made by fabricating top plate and bottom plate with seamless pipe.

5.4.2. New Cost Analysis:

1. Cost of fabricated components (Raw material) = Rs 8000
2. Fabrication cost = Rs 3000
3. Total cost per housing = Rs 11000
4. Cost of new plunger = Rs 3800
5. Cost saving per assembly = Rs 20500
6. On estimated 4 presses order annually

5.4.3. Savings:

Cost Saving (Annually) = Rs 326000

5.5. Design Change Of Hydraulic Presses

Fig. 11. Hydraulic Press

5.5.1. New Method Description

Fig. 12. Hydraulic Press

1. Guiding of slide is done with top head & upright.
2. Total Press height reduced.
3. Raw Material saved for tie rods & uprights.

5.5.2. Savings:

1. Tie Rod Length Reduced by 500 mm (480 kg per press saved)
3. Savings in Plates per press = $1080 \times 46 = \text{Rs } 49600$
4. Total Savings per press = Rs 92800
5. Annual Savings (Considering 10 presses annually) = Rs 928000

6. ANALYSIS OF VARIOUS PROCESSES IN ASSEMBLY SHOP

6.1. To reduce the cycle time in machining of the ecc. Gear & process simplification For assembly

Route of work change from previous stage to assembly shop

6.1.1. New Method Description:

1. Take the match marking from the flange
2. Drilling and tapping done

3. Reset the gear
4. Take match marking
5. Drilling and tapping done

6.1.2. New Cost Analysis:

1. Expected time with this process 20hrs.
2. In terms of rupees per press $20 \times 350 = 7000$

6.1.3. Savings:

Total saving in rupees 22600 per press per year saving : $5 \times 22600 = 113000$

6.2. Cycle Time Reduction in Stud & Nut Fitting On Crown In Intermediate Shaft Assembly.

6.2.1. New method Description:

A ring gauge of suitable thread in sizes m30, m32, m36, m42 is made & sent to vendor. It worked positively. Now there is no need to check or correct the threads by machining. Hence saving of assembly man hrs and machining hrs as well.

6.2.2. Savings:

Saving in labour cost = $3 \times 400 \times 40 = \text{Rs } 48000$
 Saving in machining cost = $4 \times 450 \times 40 = \text{Rs } 72000$

7. ANALYSIS AND RESULTS

1. While designing new Pressure Relief Valve here we able to reduce the cost up to Rs.135000 per annum.
2. In the installation of modified Inbuilt Lubrication Tank we able to compensate the cost in manufacturing almost Rs. 81900 annually.
3. Fabricating new flange (Drive Shaft Assembly), here able to reduce the design cost up to Rs. 58700 every year.
4. Acting changes in Manufacturing Process of Mechanical Press will able to reduce the design cost by Rs. 326000 per annum.
5. Changing and modifying the design Of Hydraulic Presses can reduce the design cost of setup with huge amount of Rs.928000 annually.
6. While incorporating the CNC Cutting Machine the machining time reduces from 1264 to 472 Hrs with net savings of Rs. 712800.
7. Saving of Rs 25600 as no time of filling and capping is required, so time energy reduces almost 64hrs.
8. Rs 4.45 Lac by considering new Display and Rs. 1.35 Lac by considering second hand display unit. This will able to help Floor Head to surveillance the

working and operations to labors and officials more precisely will improve the productivity and machine output to extent of 10% in total.

10. Saving in machining cost = $4 \times 450 \times 40 = \text{Rs } 72000$ per month and up to 4 hours per cycle.

So while taking the estimation, the total savings roughly come out to Rs 17, 81, 100 per annum which is almost 8% of the total expenses and 1326 hours of work energy saved by installing the new techniques.

8. CONCLUSION AND RECOMMENDATIONS

In ISGEC productivity increased by analyzing various processes in SHOPS:

1. Productivity increased in terms of time, capital, labour, material which can be seen from the result obtained above. It also shows the extent of benefits to the concerned company.
2. Improved productivity helped ISGEC to increase its turnover and to meet customers' order within time.
3. The productivity improved is sustainable in nature and further there is an ease of operation two in implementing the various suggested alternates manufacturing techniques.
4. Productivity can be improved further by Ergonomics as it directly enhances a worker's ability to carry out his operations on different machines.

Mobile Payment Adoption in India: Challenges and the Way Forward

Hemantkumar P. Bulsara¹, Esha A. Pandya²

¹Applied Mathematics and Humanities Department,
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

²S. R. Luthra Institute of Management, Surat, Gujarat, India

Abstract: Over the last one and a half decades, mobile payments have achieved considerable commercial success worldwide. Mobile payments show huge potential and present a great opportunity. The immediacy of mobile payments, along with the portability of mobile devices, makes it possible for consumers to conduct commercial transactions in many situations in a rapid and comfortable manner. However, in spite of its potential, the adoption of mobile payment has been slow in many countries including India. Recent studies show that some issues are hindering consumer adoption of mobile payments. This paper aims to throw light on major challenges for consumer adoption of mobile payments in India and the way forward.

Keywords: Mobile payment, mobile devices, Mobile payment adoption

1. INTRODUCTION

Mobile payment (m-payment) is defined as “transfer of funds in return for a good or service, where the mobile phone is involved in both the initiation and confirmation of the payment” (De Bel and Gâza, 2011, p.12). The m-payment system is a significant component of an m-commerce service, because it makes an m-commerce transaction possible by dealing with the exchange of the financial values of mobile transactions. Prior studies suggest that mobile payment methods provide their customers with a number of advantages including location-free access, a wide variety of purchase possibilities, an easy alternative to cash payments and timely contact with their financial resources. As highlighted in the Ministry of Finance’s Committee report on Digital Payments published in December 2016, financial inclusion is one of the foremost policy challenges facing India today. As of 2014, approximately 53 per cent of India’s population had access to formal financial services. In this context, mobile payment can act as a key enabler for accelerating financial inclusion.

2. M-PAYMENTS GROWTH AND ADOPTION

Recently, m-payments have achieved considerable commercial success worldwide. Worldwide total transaction value in the “Mobile Payments” segment amounts to US\$224, 426m in 2017 showing an annual growth rate of 40.1% and for India, transaction value by m-payments is expected to show an annual growth rate (CAGR 2017-2021) of 138.7 % resulting in the total amount of US\$2, 572m in 2021. In the “Mobile Payments” segment of India, the number of users is expected to amount to 21.9m by 2021 (Statista research, 2017). The

major reason for the growth in India include rising smart phone penetration and internet access.

As such, mobile payment can supplement or replace cash, check, credit and debit cards in consumer daily purchase, and it can also serve as a means of entry to electronic accounts and payments. There is growing awareness that mobile payment supplies economic benefits to the society as it has significant lower costs than cash-based services and existing card payments (Arvidsson, 2014; Mallat, Rossi and Tuunainen, 2004). Furthermore, it can generate competitive advantage for enterprises via its ubiquity and convenience (Chen, 2008; Mallat, 2007). Hence promoting consumers’ usage of mobile payment services is of utmost importance for both Governments and marketers. However, Au and Kauffman (2008) find that although mobile devices are virtually ubiquitous around the world, the penetration of mobile payment has been uneven. For example, mobile payment has been popular in some developing countries where credit cards are not widely available and many people do not have bank accounts (OECD, 2012). Mobile payment adoption in developed countries exhibits different patterns too. Studies show that mobile payment has not been widely adopted in the U.S. (Hayashi, 2012; Pope et al., 2011). Japan and Korea are successful with mobile payment adoption (Amoroso and Magnier-Watanabe, 2012; Pope et al., 2011). Pope et al. (2011) studied mobile payment adoption in U.S., Singapore, Hong Kong and India and concluded that mobile payment is still at an infancy stage. According to the MasterCard mobile payments readiness index, no country has achieved a mainstream consumer acceptance, and we are still in the early days for the adoption of mobile payments globally (MasterCard, 2014). For a successful implementation of mobile payment

services, it is crucial to understand the challenges which stand in the way of m-payments.

3. METHODOLOGY

The methodology used for this study is based on secondary information available mainly from online publications by reputed bodies such as BGC-GOOGLE, EY, MasterCard, OECD and Ministry of Finance, GOI. Data has also been collected with the help of various articles, journals and websites.

4. CHALLENGES TO THE CONSUMER ADOPTION OF MOBILE PAYMENTS IN INDIA

4.1 Security Concerns and Lack of Trust in Mobile Payments

When innovative technologies such as contactless mobile payments are adopted, security becomes a vital issue (Loilier, 2013). There is a common consumer perception that mobile payments are insecure (Cyril et al., 2008). In mobile payment transactions, credit card number and care verification value code (CVV) are often transmitted. Wireless networks are vulnerable to attacks and mobile encryption systems are less robust than traditional encryption systems (Misra and Wickamasinghe, 2004). These security concerns increase users' perceived risk and decrease their usage intention toward such systems (Zhou, 2011). Though some security practices are in place, primarily using cryptography, there are no clear standards on protection of payment card information in such transactions from regulatory bodies. If security concerns are a major barrier to mobile adoption, it stands to reason that trust is a key component to overcoming that barrier. However, resolving security issues will not automatically help to gain this trust. It is of more importance, however, to convince the consumers about the security of m-payment systems. This can be done with the assistance of proper marketing channels as well as advocacy from reputable institutions.

4.2 Digital Literacy of Consumers

A large segment of the target population is not comfortable with the use of mobile technology and many consumers are facing English language barriers. Service providers will need to invest in simplifying the technology and interface, providing multilingual interfaces and more importantly, educating customers about using mobile technology (EY analysis, 2016).

4.3 Speed of Transaction

The speed of mobile payment transactions is still slow, especially at the POS, where consumers and merchant look for a quick turnaround. Moreover, in areas of poor connectivity, transactions often fail or time out. This results in a poor consumer experience, which dis-

incentivizes them from making mobile payments (EY analysis, 2016).

4.4 Complexity of Usage

Product complexity is considered to be one of the biggest reasons behind non-usage of digital payments (BCG-Google Digital Payments, 2020). As digital payments target heterogeneous user and merchant segments across the value chain, product design needs to ensure that the solution is built for the base and communicated appropriately. This is critical for universal acceptance. In comparison, cash is still the most preferred instrument of payment, simply because of its absolute ease of understanding even though it is not the most convenient option. Payment innovations have to ensure increasing simplicity of the product.

4.5 Habit to Use Cash

A large percentage of the Indian population is still habituated to cash even when making online purchases. Consumers also feel that spending money in cash aids in budget management and keeps spending patterns in check. Although they acknowledge that handling cash is inconvenient, they are satisfied with the way it works and are not enthusiastic about changing how they handle money very easily as it is so ingrained in their day-to-day life (Google-BCG Market study, 2016).

4.6 A Perceived Lack of Compelling Value Proposition

As per the market study by Google-BCG (2016), about a half of the users could not fully comprehend the benefits or value of using digital payments. It is evidenced in the fact that they have not heard a lot of people use or talk about digital payments. This does not give them a very strong motivation to alter behavior or adopt digital payments.

4.7 Inconvenience, Low Reach and Possibility of Making Mistake

According to the market study by Google-BCG (2016), consumers who have used mobile payments have indicated that inconvenience of remembering login credentials, insufficient acceptance of m-payments, possibility of a technical or human mistake during a transaction and frequently running out of balance are the top reasons for not using m-payments.

5. THE WAY FORWARD

In order to acquire customers to use mobile payments, certain key points need to be addressed by the payment service providers, regulators and government.

Triangulating information from multiple data points (such as customer and merchant transaction analysis, location, device fingerprinting and value-volume thresholds) can help in developing algorithms to contain risks and pre-empt frauds.

This will help build consumer and merchant trust in the system.

The m-payment offerings can be made more appealing through incentives such as tax rebates, waiver of transaction fees and charges to enable adoption. The user interface of m-payment solutions needs to be simple and intuitive to ensure a seamless customer experience. To drive mass adoption expanding merchant acceptance is critical. Acquisition and integration of merchants under the system would increase the use cases and thereby increase acceptance of digital payments.

Providers should focus on educating customers considering the low digital literacy and communicate the usage benefits clearly. To overcome English language barriers, specifically for customers from tier II and tier III cities, the providers should start offering multiple regional language interfaces. Prominent m-payment players such as Paytm and MobiKwik have already developed such interfaces.

To win back churned consumers, payment service providers need to address critical pain points. For example, introducing biometric authentication would eliminate the need of multiple user names and passwords. Auto-sweep features can aid in addressing low account balances and the maintenance of requisite minimum balances in the digital payment account.

High frequency transactions should be brought under the ambit of digital payments to urge consumers' movement in that direction. In order to make a decisive move towards a less cash society, it is imperative that transacting through electronic mode is as attractive as transacting with cash. In this regard, RBI can opt for designing a pricing strategy that would influence the payment behaviour of customers which encourages use of electronic products over cash and paper based products. Also there is a need for expanding the acceptance infrastructure such as ATMs, PoS terminals, micro-ATMs, handheld devices etc. Use of modern technology such as mobile PoS could be explored to cover the large base of retailers across the country.

A joint policy-making or go-to-market approach on mobile payments by the industry players, facilitated by payments bodies can help in expanding the market and increasing adoption. Such policy decisions for facilitating mobile payments can take into consideration the requirements of prepaid operators, banks and telcos for building and scaling up the infrastructure and transaction rails required for payments. The Government can possibly bring in restrictions that limit transactions done in cash beyond a defined threshold. The regulators and payments bodies also need to act as facilitators by taking initiatives such as standardizing merchant acceptance norms to simplify the merchant onboarding process.

6. CONCLUSION

Cash transactions continue to be the dominant form of payments, and users — especially from low-income groups — prefer cash to digital forms of payments. Getting customers informed about and comfortable with the new platforms will be pivotal to the widespread uptake of mobile payments in the country. The major challenges for Indian customers include security and trust issues, lack of digital literacy and language barriers, complexity of usage, lack of knowledge about the benefits of m-payments and high dependency on cash. India must learn from other countries in the developing world, which have managed to reduce their dependence on cash even while bringing in more people in the folds of the formal banking system. The success of mobile payments hinges on institutional initiatives, product and process innovation from operators, a supporting regulatory environment and channelized efforts of the industry players toward a common objective.

The path forward is clear:

- The government should invest in building the required financial and digital infrastructure
- A nationwide financial and digital literacy campaign accompanied by a medium-term strategy to improve access to, and awareness of, electronic payments. Targeted financial education programmes can improve financial skills and credit management, and increase account ownership
- The government must undertake the herculean task of changing attitudes towards digital payments among customers and merchants.
- Regulators should put in place all necessary cyber security measures and providers of m-payments should develop easy to use, flexible and multilingual m-payment solutions to cover customers from all segments.

Use of Big Data tools in PLM

Krishna B. Hande, Vilas M. Nandedkar

Department of Mechanical Engineering,
Shri Guru Gobind Singhji Institute of Engineering and Technology, Nanded, Maharashtra, India

Abstract: Most large enterprises store a tremendous volume of transactional data, trillions of information consisting of customer details, suppliers and data related to different phases of product life cycle management. There is an exponential growth in amount of data. To overcome these complex data much work is being carried out. The main aim of this paper is to highlight Big Data tools that can be used during the various data involved in three phases of product lifecycle management. The paper also describes the advantages of Big Data tools (Hadoop) in product lifecycle management.

Keywords: Big Data, Product Lifecycle Management.

1. INTRODUCTION

Nowadays data is being produced on a large scale from different sources. The different sources may be manufacturing industries, banking sectors, health organizations, transportation and logistics, government systems, education systems etc. This data needs to be stored at some particular location so that it can be retrieved efficiently whenever needed. Before introduction of Big Data, the companies were not able to store tremendous data for longer periods because of limited data storage capabilities, which would force them to delete the previous data (Ahmed et. al., 2017).

International data corporation stated that service sector and manufacturing sector both created over 1600 Exabyte data during the year 2015. The data volume is generated at a rapid speed because of the digital revolution and advancement of information technology such as ubiquitous –sensing mobile devices, aerial sensory techniques, Internet of things (IoT) Technologies, microphones, cameras and wireless sensor networks (Zhong et. al., 2016). Such datasets are huge and unstructured, ambiguous. Therefore it is a difficult task to handle these data using traditional database management systems.

2. ABOUT BIG DATA

“Big Data” refers to datasets whose size is beyond the ability of typical database software tools to capture, store, manage and analyze. The given definition is subjective which incorporates moving information of how big a dataset needs to be in order to be considered Big Data –i.e. the Big Data is not defined in terms of being larger than a certain terabytes of data. We consider that, as there is advancement in technology, the size of datasets that qualify as Big Data will also increase (Manyinka et. al., 2011).

2.1 Characteristics of “Big Data”

“3Vs”, which is generally accepted three defining dimensions of “Big Data” were introduced in the year 2001

viz. ‘Volume’, ‘Velocity’ and ‘Variety’. Two more “Vs” are introduced nowadays, ‘Variability’ and ‘Value’ (Jingran et. al., 2015).

- Volume: huge amount of data is produced per second. “Big Data” is capable of storing this data (certain no of terabytes) which is referred to as Volume
- Velocity: Data is being generated fast and it is need to be stored fast. If the processing time of system increases then decision taking time will also increase which will lead to miss opportunities.
- Variety: The data which is getting generated may be of different formats, types and structure this variation of data is referred to as variety.
- Variability: Expansion in the range of values of data is referred to as Variability. The difference between Big Data and traditional datasets is that traditional datasets always represent low variance than Big Data.
- Value: While feeding the data in the systems it is important to know that which data is important and which is to be not recorded. Valued information can be produced and can be used in business operations by using data analytic methods. This is referred to as Value.

3. ABOUT PLM

A strategic business approach that applies a consistent set of business solutions in support of the collaborative creation, management, dissemination, and use of product definition information across the extended enterprise from concept to end of life—integrating people, processes, business systems, and information (Jingran, et al, 2015). Product Lifecycle Management (PLM) is the business activity of managing, in the most effective way, a company's products all the way across their lifecycles. Product's lifecycle includes the data related to the idea of

the product, the data when it is being defined, the data when it is being realized, the data when it is used and when it is to be disposed of (Arbor, 2002).

Three of the lifecycle phases (Imagination, Definition and Realization) make up the Beginning-of-Life (BOL) of the product. There is a Middle-of-Life (MOL) phase which includes activities such as product use, support and maintenance. There is an End-of-Life (EOL) phase which includes activities such as product retirement, disposal and recycling (Jingran, et al, 2015).

4. PHASES OF PLM

As discussed above in the introduction of PLM the different stages of product lifecycle management are as follows

- BOL(beginning of life)
- MOL(middle of life)
- EOL(end of life)

4.1 Beginning of Life

In order to develop a new product in market, planning is done well before the production. The data in the beginning of life consists of idea generation, idea evaluation, feasibility analysis, technical research and development, product (market) research and development, preliminary production, market testing, commercial production, product introduction.

TABLE 1: Data in Beginning of Life

Category	Main data	Category	
Customers' demands	Product function, configuration, packaging, quality, cost, brand, and other related expectation Design	Design specifications	Materials list, suppliers list, electronic drawings, computer programming codes, configuration parameters, location parameters, tolerance parameters, intensity of materials, etc.
Maintenance and failure Information	Main breakdown problems, frequency of maintenance, failure rate, critical component list, root causes, etc.	Production information	Assemble instruction, production specifications, production history data, production plan, inventory status, etc.
Cooperative corporation Information	Alternative supplier information, alternative outsourcing company information, etc.		

4.2 Middle of Life

After the product is launched in the market, the attention should be focused on the service. Middle life of product consists of data related to logistics, distribution, use, service and maintenance.

TABLE 2: Data in Middle of Life

Category	Main data	Category	Main data
User manual	Product function introduction, installation guide, use condition, precautions, etc.	Product status Information	Degree of quality of each component, performance definition, etc.
Production Information	Assemble instruction, production specifications, production history data, production plan, inventory status, etc.	Usage environment Information	Usage condition (e.g., average humidity, internal/external temperature), user mission profile, usage time, etc.
Maintenance supporting information	Spare part ID list, price of spare part, maintenance/service instructions, etc.	Maintenance Plan	Maintenance engineers, tools, dates, places, costs, failure causes, etc.

4.3 End of Life

After the product is put into service, it eventually wears out or becomes obsolete because a better product comes into the market. At this stage one option is to junk the part and dispose of it in some way that eventually returns the

material to the earth. This data related to the product's disposal is involved in the end of life of product. By knowing the history of information of maintenance usage environment information and product status information from middle of life degradation status and value of individual components can be calculated.

TABLE 3: Date in End of Life

Category	Main data	Category	Main data
Maintenance history Information	Components' IDs in problem, installed date, maintenance engineers' IDs, list of replaced parts, aging statistics after substitution, maintenance cost, etc.	Recycling part information	Reuse part or component, remanufacturing information, quality of remanufacturing part or component, etc.
Product status Information	Degree of quality of each component, performance definition, etc.	EOL product status information	Product/part/component lifetime, recycling/ reuse rate of each component or part, etc.
Usage environment Information	Usage condition (e.g., average humidity, internal/external temperature), user mission profile, usage time, etc.	Dismantling information	Ease to disassemble, reuse or recycling value, disassembly cost, remanufacturing cost, disposal cost, etc.

5. BIG DATA TOOLS (HADOOP) APPLICATIONS IN PLM

Traditional technologies lag behind in providing high performance and capabilities of processing data quickly. Hadoop fills a gap in the market by effectively storing and providing computational capabilities over substantial amounts of data. Hadoop rapidly processes large data sets by using its parallel clusters and distributed file system. There is no load on network and servers as Hadoop performs its task where data are stored whereas the traditional technologies copy in memory all distant data to perform executions. Hadoop consists of fundamental units viz. Hadoop Distributed File System (HDFS), MapReduce framework and YARN (Yet Another Resource Negotiator)(described in the following sections).In addition, modules can be added by the users according to their requirement e.g. capacity, performance, reliability, scalability, security etc.

5.1 Data Storage Using Distributed File System:

Storing Big Data in any system was a problem. Thus Hadoop came up with Hadoop distribution File System to solve this problem. The Big Data which is to be stored in the master system is divided into multiple churns of data in different slave systems. HDFS has two main daemons one is NameNode and the other is Data node. Namenode is a master daemon which runs on the master machine that is of

high end essentially and Data Node is a slave machine which runs on the commodity hardware. There can be one NameNode and multiple DataNode. NameNode records the metadata (location of blocks stored, size of the files, permissions, hierarchy etc). It receives time to time reports from the DataNode. Thus it manages the Data Nodes. Data Nodes are the slave daemons which store the actual data, it serves read and write requests from the clients. The slave machine is connected to the master machine by core switch at the same time the slave machines are interconnected. Each file is stored in HDFS as blocks as it is a distributed system. Hadoop creates replica of each block that get stored into the Hadoop File Distribution System thus it is a tolerant system (Ahmed et. al., 2017).

5.2 Data Processing using MapReduce:

MapReduce is a programming for data processing. Different language programs such as Java, Python, and Ruby etc can be written in MapReduce. The programs written in the MapReduce are parallel. The processing in the Map Reduce is broken in two phases: the Map phase and Reduce phase. The programmer also specifies two functions the map function and reduce function.

Map function: The input data (long text files) is divided into independent data partitions constituting key-value pairs.Mapper processes each key value-pairs individually and tasks Across the master controller.Unique compute

node is assigned to each data partition. At this stage, the framework is charged to collect all the intermediate key-value pairs, to sort and group them by key.

Reduce function: The intermediate output data is processed by the Reduce function. The reduce function combines key-values working with one key at a time. Later it finds the average of values given in by the mapper. Then it produces list of output Key-value pairs and finally these output Key-value pairs are stored in the output file.

For scheduling purpose, the NameNode runs a instance called JobTracker. It sees whether slave nodes have assigned tasks or not. If not then it reassigns the task. Similarly the slave nodes run the TaskTracker instance which will work same as the JobTracker works for the master nodes (Ahmed et. al., 2017).

5.3 Data Processing Using YARN:

YARN (Yet Another Resource Negotiator) is a core component of Hadoop 2.0 and it is added to provide improved performance in the Hadoop world. YARN is next generation of the Hadoop computing platform which offers various advantages compared to MapReduce in first version of Hadoop. YARN/MapReduce 2.0 is introduced in the Hadoop 2.0. It is a layer that separates the resource manager layer and processing component layer. MapReduce 2.0 moves the resource manager (like infrastructure to monitor nodes, allocates resources and schedule job) into YARN.

JobTracker responsibilities in MapReduce 1.0 is now split into two daemons in YARN/MapReduce 2.0

Resource manager: It manages the resource allocations in the Hadoop cluster. Resource manager consists of two components –scheduler and application manager. Resource manager is a global resource scheduler which manages and allocates cluster resources. It is responsible for tacking the resources and also scheduling the applications.

Application Master: Manages application life cycle and task scheduling. It can interact with the resource manager as well as the Node Manager. Application is job submitted to the framework.

YARN is a more isolated and scalable model than the MapReduce 1.0 system where a single JobTracker does all the resource management, scheduling and task monitoring work (Ahmed et. al., 2017).

6. ADVANTAGES OF BIG DATA TOOLS IN PLM

Improving the quality and innovation of design of product: Quality and innovation in the product design can be improved by using Big Data tools. Most of the companies today believe in market driven supply chain. They are serious about the customer service. the companies want feedback from the customers so that they come to know what the customers want . Thus the customers get

involved in the design phase. For example, Xiaomi Company in China is a typical successful representative (Arbor, 2002).

Improving the accuracy, quality, and output of production: Nowadays most of the companies are being fully automated. Once the raw material enters the industry all the remaining processes are performed by CNC machines. Therefore these CNC machines produce a large amount of data in very less time. Big Data tools help to store this Data accurately.

Accurately forecasting product demands: By conducting surveys the customer needs can be predicted. Big Data tools helps in carrying out such surveys knowing the customer needs. By collecting this data using Big Data tools like Hadoop forecasting can be done, which may prove efficient for any industry

Data Storage in PLM: Storing large data involved in the various phases of product lifecycle management is now possible by using the Big Data tools. The data stored is secure and can be retrieved very fast, as the processing speed of Big Data tools is very fast. Manufacturing companies store a large amount of product related data. They use this data for in their new projects so it is essential for them to store it securely, which is done by using Big Data tools.

7. CONCLUSION

Big Data has emerged as an element which is able to provide solutions for handling the tremendous data. Big Data tools (Hadoop) can be used in the different phases involved in the product lifecycle management. Big Data tools can be proved to be efficient for industries as it is very economical. Certain Big Technical giants use this technology and in future Big Data tools will be used almost by all companies.

The Internet of Things in Product Life Cycle Management

Bungai Gaganpreet Singh T.

Department of Mechanical Engineering,
Shri Guru Gobind Singh ji Institute of Engineering & Technology, Nanded, Maharashtra, India

Abstract: *The Internet of Things belongs to the ever growing network of physical objects which feature an IP address for internet connectivity, and communication that occurs between these objects and other Internet-enabled devices and systems. IoT has attracted lots of attention from all over world recently. It is a system where daily used objects can be equipped with, sensing, identifying networking and processing capabilities that will allow them to communicate with one another and with other devices and services over the Internet to accomplish some objective. Successful applications of IoT have been implemented in many fields. Today, expectation from Internet of Things (IoT) is extremely high worldwide. Internet of Things can provide a good opportunity to build a powerful industrial system; also it can be used in PLM industries. A wide range of industrial application have been developed and deployed in recent years. This paper reviews the concept of Internet of Things (IoT), important technology in IoT, major application of IoT. Moreover it discusses concept of Product Lifecycle Management (PLM), application of Internet of Things (IoT) in Product Lifecycle Management.*

Keywords: *Internet of Things (IoT), Product Lifecycle Management (PLM), RFID, Closed loop PLM, Mechanical Engineer.*

1. INTRODUCTION

Internet of Things (IoT) refers to the strong connectedness between digital and physical world. Over last couple of decades, there is a continuous evolution in the Internet of Things technology. IoT has implemented in many areas. The term IoT was initially proposed to refer for uniquely identifiable interoperable connected object with Radio Frequency Identification technology (RFID). As Internet of Things technological revolution continues to take hold of industries worldwide such as energy manufacturing, healthcare services, and transportation, industry leaders are looking for ways to gain the analytical insight that IoT technology promises.

Product Lifecycle Management (PLM) is a new paradigm for manufacturing companies. As its name describes, Product Lifecycle management allows companies to manage their products across their lifecycles – from the basic idea for a product to the end of its life. This is one of the most important activities in any manufacturing company. Successful applications of IoT have been demonstrated in many fields. New technologies enable the IoT in the world of Product Lifecycle Management (PLM) to bring digital product and digital manufacturing to the next level.

In order to become smart, manufacturing industries need to employ new intelligent methods of production and target a marketplace in which real time information is exchanged between products and machine services.

With IoT technology, the PLM process continues out into the field, allowing all stakeholders in the product's lifecycle from initial design, in manufacturing of product to gain visibility into how the product is performing and being used by its customers. In this paper the concept of IoT as well as PLM introduced and the successful application of IoT in Product lifecycle Management (PLM) system is analyzed.

2.1 Concept of IoT

The term “Internet of Things” (IoT) was first proposed in 1999 by British technology pioneer Kevin Ashton in MIT's Auto ID centre, a global research network of academics laboratories focused on RFID and IoT technology. Internet of things (IoT) is defined as the interconnection via the Internet of computing devices embedded in everyday objects, enabling them to send and receive data (Navid, 2016)). IoT can be considered as a global network infrastructures composed of numerous connected devices that depends on sensory, communication, networking and information processing technology.

The basic technology for IoT is Radio Frequency Identification (RFID) technology which allows microchips to transmit the identification to readers through wireless communication. By using RFID readers peoples can identify, track and monitored any object attached with RFID tags automatically. Another foundational technology for IoT is wireless sensors network (WSNs), which mainly use interconnected intelligent sensors to sense and monitoring. The advancement in both RFID and WSN significantly contribute to the development of IoT. Today, the Internet of Things has become a famous term for

describing scenarios in which Internet connectivity and computing capability extend to a variety of objects, devices, sensors, and everyday items.

There is no universally accepted definition for the term IoT. Different definitions are used by various groups. Here we consider following definition of IoT among several.

“The term “Internet of Things” (IoT) denotes a trend where a large number of embedded devices Employ communication services offered by the Internet protocols. Many of these devices, often

Called “smart objects, ” are not directly operated by humans, but exist as components in buildings or

Vehicles, or are spread out in the environment.”

2.2. Characteristics of IoT

Gathering from existing reports and research documents, the characteristics of IoT are concluded (kavyashree G Chandrasekhar, 2016).

2.2.1. Intelligence

IoT comes with combination of algorithms and computation, software and hardware that makes IoT smart. Ambient Intelligence in IoT enhances its capabilities which facilitate the things to respond to in an intelligent manner to a particular situation and support them in carrying out specific operation.

2.2.2. Connectivity

Connectivity empowers Internet of Things by bringing together everyday objects. Connectivity enables network accessibility and compatibility in the things. Intelligence in IoT enhances its capabilities which facilitate the things to respond to in an intelligent manner to a particular situation and support them in carrying out specific operation.

2.2.3. Dynamic nature

The primary activity of IoT system is to collect data from its surrounding environment; this is achieved by the dynamic changes that take place around the devices.

2.2.5. Sensing

IoT would not be possible without the use of sensors which will detect or measure any changes in the environment to generate data that can report on their status or even interact with the surroundings.

2.2.6. Heterogeneity

Heterogeneity in IoT is one of the important characteristics. Devices in IoT are based on different hardware platform

and networks and can interact with other devices or service platforms through different networks.

2.3. IoT's Key components

2.3.1. Things

Things are smart, connected products and other. Things combine processors, sensors and software with connectivity.

2.3.2. Communication infrastructure

Communication infrastructure includes wired or wireless (Wi-Fi, 4G, Bluetooth and LAN) network connects things to the internet and each other.

2.3.3. Computing infrastructure

Data capture and analytics tools, and new business and software applications create new forms of value.

2.4. Applications of IoT

Although IoT is an emerging domain, it did help a lot to enable or enhance countless applications, which has brought numerous changes into our daily lives. According to the survey that the IoT-I project ran during 2010, 65 IoT application scenarios were identified, grouped in 14 domains: Transportation, Smart Home, Smart City, Lifestyle, Re- tail, Agriculture, Smart Factory, Supply chain, Emergency, Health care, User interaction, Culture and tourism, Environment and Energy. The major 54 applications in 12 domains of IoT are illustrated in fig. 2.1.

Fig. 2.1 Major application of IoT (Fei & Y, 2016)

3. PRODUCT LIFECYCLE MANAGEMENT (PLM)

3.1. Concept of PLM

PLM manages the all product data from conceptualization to finished product. PLM is a strategic approach and has three fundamental dimensions: (i) universal, secure, managed access and use of product definition information, (ii) maintaining the integrity of that product definition and related information throughout the life of the product or plant and (iii) managing and maintaining business processes used to create, manage, disseminate, share and use the information. In order to face the new industrial challenges such as environmental changes (mass customization, short product development lead time, high complexity of product functions), increasing collaboration (intra-enterprise, extended supply chain), importance of growth of Web based paradigms and technology, digital manufacturing, customer service as well as decision support services, the information loops along the whole product lifecycle have to be closed. The stakeholders have a general desire to enable the seamless flow, tracing and updating of information about a product, after its delivery to the customer and up to its final destiny (decommissioning, deregistration and EOL) and back to the designer and producer (Kiritsis, 2009).

3.2. Benefits of PLM

PLM provides benefits throughout the product lifecycle. Examples include getting products to market faster in the Beginning-of-Life, providing better support for their use during the Middle-of-Life, and managing their End-of-Life better.

With its focus on the product, companies are looking for PLM to provide benefits in four main areas shown in fig 3.1 (Stark, 2005).

4. THE INTERNET OF THINGS AND PRODUCT LIFECYCLE MANAGEMENT

For product development process the product data management and information technology based PLM are central concept. The concept of PLM can be considered as an evolution of product data management, so we can say that concept of PLM is derived out from PDM.

PLM is strategic approach which considers a product over its entire lifecycle. Each lifecycle phase consists of particular rules, production and information set which are required for lifecycle phases. The Product lifecycle can be divided into three phase as following.

BoL- Beginning of life (BoL) phase contains the conceptualization, design and production of product. First an idea or concept is developed then product concepts and their implementation and verification are developed.

MoL- In Middle of Life phase product is used by customers. In this phase challenge is to understand the consumer and to maintain and/or repair product.

EoL- When the product is eventually withdrawn from market, the End of Life phase is started. Generally the product is returned to the manufacturer to disassemble and recycled. The details of product parts and material can be used again.

During all these three phases the large amount of data is produced and maintaining and controlling of these data is difficult. Product data generated during MoL and EoL can use as feedback for designing a new product for generating conceptualization and design. IoT approach in PLM is can applied at all three phases of Product during its life. There is a general requirement of many stakeholders in the product supply and value chain (from designers to users and recyclers) to enable the seamless flow, tracing and updating of information about a product, after its delivery to the customer and up to its final destiny (decommissioning, deregistration and EOL) and back to the designer and producer. This is illustrated in fig. 4.1, where dashed thick lines represent material flow along the product lifecycle including 'recycling' loops, while dotted lines represent information loops (Kiritsis, 2009). The objective here is to allow information flow management to go beyond the customers and to close the product lifecycle information loop and enable the seamless e-transformation of product lifecycle information to knowledge.

Fig. 4.1 Feedback of MoL and EoL for new product (Kiritsis, 2009)

During production, by collecting and analyzing data by sensors embedded in products and systems, organizations can start to optimize use and production, determine if particular parts has started to fails, and if the product or

piece of equipment is operating in the field as it was designed to.

Manufacturers have already started investing in hardware, software, and networking systems across the world and developing strategies to build the Internet of Things (IoT) and Services architecture to capitalize upon its benefits.

Among IT applications in digital factory, PLM is critical for the integration and management of information. PLM is important for the integration and management of information. Hence we use a PLM system to represent the digital factory in this work. Figure 4.2 illustrates our system architecture for the integration between the 'IoT platform' and 'PLM'. The role of the PLM system is to collecting and managing data of products, processes, definitions, resources and decisions across the whole product lifecycle supporting changes and enabling traceability of these changes. The IoT layer is used to collect large amounts of real time data, normally used for monitoring, controlling and planning on the shop floor. The real time information comes from various sources such as temperature pressure sensors or machine controllers. The difference between the IoT layer and the PLM layer is the database type to store data. Unique identifiers of products or parts are important for the PLM application during the lifecycle because products in PLM are used not only inside the enterprise but also in a distributed and collaborative environment.

Fig- 4.2 System architecture of IoT based Factory
(Navid, 2016)

In the IoT layer large amounts of data are collected and stored in an unstructured way and in real time databases.

In Middle of Life; Until a moment ago, PLM technology only continued through the lifecycle until the product rolled off the production line and was put into use. This meant that any failures or issues that occurred had to be manually reported by the customer themselves.

Now using IoT, the PLM process continues out into the field, allowing all stakeholders in the product's lifecycle to gain visibility into how the product is performing and being

used by its customers – without waiting for customers to volunteer this information. Engineers are able to automatically make crucial edits to the product that manufacturing can begin integrating immediately. By monitoring product the minor issues can be spotted and fixed before they grow into large issues that can halt the product's use causing downtime that can severely affect customers' bottom lines. By using IoT we can stay connected with product and monitor product using sensors. By monitoring the product in the field, minor issues can be spotted and fixed before they grow into larger issues that can halt the product's use.

In End of Life (EoL), PLM systems can predict remaining lifetime of parts and components based on usage data generated by IoT. Predicting remaining lifetime of parts or components: In most cases, while a product cannot be used any longer, different level components still have value. Predicting remaining lifetime of parts or components helps to decide what to recycle and what the re-cycle level it should be. The combination of sensors and their autonomous coordination and simulation based on IoT will help to predict the occurrence of breakdown and the relatively accurate remaining lifetime of parts or components by analyzing history data combining with corresponding component ID.

IoT and PLM system will allow all the actors who play a important role during the lifecycle of a product (i.e. managers, designers, service and maintenance operators, recyclers, etc.) to track, manage and control product information at any phase of its lifecycle (i.e. design, manufacturing, MOL and EOL), from any place in the world and at any time.

Integrating IoT with PLM, many companies are adding sensors to new or existing products stationed everywhere in field or on factory floors to in a customer's house or working area, or even on the move with fleets and cargo. Using the data produced from sensors and IoT, PLM software is helping companies and manufacturers to monitor product for its entire lifecycle.

We can collect data from a fleet of similar smart products that are distributed all over the world, and we can collect data from each unique combination of dissimilar assets that we can find gathers you find together.

5. CONCLUSION

The IoT has gained significant attention over the last few years. With the advances in sensor hardware technology and cheap materials, sensors are expected to be attached to all the objects around us, so these can communicate with each other with minimum human intervention.

Also IoT and PLM are today's fastest growing technology which will have great impact on future product. IoT has

demonstrated successful application in many fields. Product lifecycle management is establishing new industrial standard for managing company's product. By combining IoT with PLM we stepping closer to next industrial revolution.

Standardization of Material Handling Process through VSM and VSD Approach – A Case Study

Tarakanta Barik¹, Rishish Pandey²

¹Regional Logistics India (Strategy and Governance), Bosch Limited, Bangalore, Karnataka, India

²Material Logistics, Bosch Rexroth (India) Private Limited, Ahmedabad, Gujarat, India

Abstract: This research work is done to solve the very crucial and live problem of material handling process of various firms. Previously, the firms were working with presumed and gut-feeling values of the people involved in material handling process. Therefore, this research work was to replace the method with more robust and reliable method through the use of various literature and analysis.

The major aim of the research work is to map the current material handling process using value stream mapping (VSM) tools and also to increase productivity in warehouse as well as production. So a proposed process design was developed with the help of value stream design to eliminate nonvalue added activity in the process. Last but not the least, research work also involved time and man power savings in material handling process.

Keywords: Value Stream Mapping (VSM), Value Stream Design (VSD), Process Activity Mapping, Brought Out Parts (BOP), Standardization, Material Handling Unit (MHU)

1. INTRODUCTION

Warehouse management has retained its high demand in today's scenario despite the evolving supply chain management optimization techniques like lean manufacturing and just-in-time (JIT) techniques. Traditionally, warehousing was regarded as a waste in a logistics network. However, some warehouse and distribution facilities are being asked to go beyond simply stock inventory. Manufacturing and warehouse facilities are merging together to create cohesive units that are flexible to the changing requirements of the customer. Warehouse facilities are being asked to assemble, package, and ship inventory in some industries. The inventory could be raw material, work-in-process (WIP), or finished goods. This study is to review & understand the difficulty of handling, storage & issue of material. The firms which have probably the widest range of product families, the main problem for these plant maximum suppliers supplying parts in nonstandard packaging & most of the parts received in poor condition. All these components are repacked/repalletized in the Plant to store or to service it to the production line. In such a condition it is quite difficult task for store team all components in proper condition.

The major aim of paper is to define proper weight standard of material packets & define standard quantity for all components. Also aim of the paper is to define identification standard for each component & ensuring that should be feasible for line & easy for accountability.

The objective of the paper is to design standard material handling unit to ensure that material received from the

supplier can be stored as it is and can also be serviced on the production lines as it is.

The other objectives of paper are given below:

- Define packaging for BOP considering weight & qty to have minimum impact on cost
- Quality of material handling unit to be improved to avoid damages during transit
- To make storage more visible, easy to identify & easy to handle the components
- Proper identification for all incoming BOP
- Reduce no of man power used for material handling
- Standard material handling unit size for brought out part

The deliverables of research work are given below:

- Reduce manual handling activity inside store
- Eliminate NVA activity where ever possible
- Reduce Material handling casual from 14 to 8
- Improved Quality of storage

The rest of this paper is organized as follows. Section 2 briefly reviews the literature on. Section 3 presents the proposed method for. Case study is conducted and described in Section 4. Furthermore, discussion on future aspect is described in section 5. Finally, conclusions are presented in Section 6.

2. LITERATUREREVIEW

Warehousing and material handling remain important areas in the supply chain of organizations today. Organizations are focusing on their logistics strategy in order to reduce costs and better serve customers. According to the 2003 Survey of Career Patterns in Logistics conducted by Bernard J. La Londe and James L. Ginter of Ohio State University, the importance of warehousing in logistics has been growing in the 1990s and into 2003 (p. 12). A number of researchers demonstrated about the material handling process. The material handling practices of warehouse and distribution facilities can have a significant impact on overall profitability for an organization. Warehousing represents the largest operational cost in the supply chains of organizations (Vega, 2004). It can represent 2 to 5 percent of the costs of sales of a corporation (Frazelle, 2002b, p. 3). Thus, an emphasis on material handling in warehouse can help the bottom line of a company. The efficient use of space, equipment, and labor in the warehouse is an utmost concern for organizations looking to trim distribution costs. Fast and efficient movement of large quantities of raw materials, component parts and finished goods through the warehouse, coupled with timely and accurate information about the products being stored, are the goals of every logistics system. These goals have received increasing attention from top management of many organizations.

There are three basic functions of material handling process:

- a) Movement
- b) Storage
- c) Visual Management
- d) Packaging Process

2.1 Movement: Recently, the movement function has been receiving the most attention as organizations focus on improving inventory turns and speeding orders from manufacturing to final delivery.

The movement function can be further divided into several activities, including:

- Receiving
- Transfer or Putaway
- Order picking / selection
- Shipping

2.2 Storage: It can be performed on a temporary or semi-permanent basis. Temporary storage emphasizes the movement function of the warehouse and includes only the storage of product necessary for basic inventory replenishment. Temporary storage is required regardless of the actual inventory turnover.

Semi-permanent storage is the storage of inventory in excess of that required for normal replenishment. This inventory is referred to as buffer or safety stock.

2.3 Visual Management: It occurs simultaneously with the movement and storage functions. Management always need timely and accurate information as it attempts to administer the warehousing activity. Information on inventory levels, throughput levels (i.e. amount of product moving through the warehouse), stock keeping locations, inbound and outbound shipments, customer & supplier data, facility space utilization and personnel is vital to the successful operations of a warehouse.

It is important to eliminate any inefficiency in movement, storage and information transfer within the warehouse. The information derived from bar code tracking can also be used to generate and electronically transmit an Advance Shipping Notice (ASN).

2.4 Packaging process: It is often a multi-step operation that involves several different workstations or areas. Once considered the back-end of the operation, there is a growing recognition that packaging and shipping play an integral part in achieving high levels of customer service. In fact, many companies now consider these functions to be the key elements in streamlining the flow of products and information through the distribution chain. Packaging has a significant impact on the cost and productivity of logistics. Automating many of these steps can greatly improve throughput and avoid errors.

3. METHODOLOGY

The research work has following four phases.

Fig. 3.1

Fig. 3.2

4. CASE STUDY

In this section, a detailed case study is illustrated with the above methodology. ABC Ltd. is a leading manufacturer of industrial components and systems in India, supplying to industries such as automotive, steel etc. in the country. This study has been carried out at ABC Plant. The plant is designed for meeting increased demand of product across the country in all segments. Also this plant is associated with the reputed OEMs to meet their demand.

This study is to review & understand the difficulty of handling, storage & issue of material related to the Bought out Parts (BOP) as well as in-house parts. Also the study includes the feasibility study of production line & supplier side as well. Then after considering all of this study define proper material handling unit (MHU) standard for all these components so that nonstandard packaging can be eliminated & reduced NVA in the plant.

The study makes a number of recommendations on how the material handling process can be improved & improve visual management in raw material store. ABC Plant has probably the widest range of product families producing industrial components. The main problem for these plant maximum suppliers supplying parts in nonstandard packaging & most of the parts received in poor condition. All these components are repacked/repalletized in the Plant to store or to service it to the production line. The objective of the paper is to design standard material handling unit to ensure that material received from the supplier can be stored as it is and can also be serviced on the production lines as it is.

In current scenario ABC Plant handling more than 80 products with 3000 product variants which is the major headache for the management team for planning & fulfill all customer demand. In such a condition it is quite difficult task for store team all components in proper condition. In present condition the plant is facing major problem of poor raw material receiving condition, nonstandard packaging material used by suppliers, no proper identification done by suppliers. The major aim of paper is to define proper weight standard of material packets & define standard quantity for all components. Also aim of the paper is to define identification standard for each component & ensuring that should be feasible for line & easy for accountability.

4.1 Value Stream Mapping of Current Handling Processes

After discussion with the co-author, the following was agreed to be the scope of the paper. The paper was to investigate the processes within the plant & the research could be handle in three phase. In starting phase study of most critical suppliers for "A" class items & recommendation for these items should be prepared & at the same time focus on Implementation. In second phase "B" class item & in third phase "C" class item to be covered. With that study of current state mapping, design of future state can be done for optimization of packaging. Implementation part can be taken care after the discussion with internal plant management team as they shown their interest towards the research.

4.2 Estimating Future Needs with Cross Functional Team (CFT)

Material handling unit designing criterias are defined as below.

4.2.1 Government Policy

As per the policy of state Government of State, each of the labor working in the industry should not handle more than 18 kg in case of male & 14 kg in case of female worker. Keeping this point the box has been designed for the BOP. This will increase the efficiency of the labor & help organization to adhere standards of policy.

4.2.2 Crush Test

During designing of the material handling units clear instruction has been given to the suppliers to maintain their material handling units strength at least 15 kg so that in transit damages can be avoided & material can reach to factory in proper condition. It will also help to workforce in case of handling.

4.2.3 Strapping of MHU

All suppliers are instructed to strap the material once it is packed in material handling units to avoid shaking while moving the part from one place to another. This will help to avoid wear & tear of box during transportation from suppliers to company.

4.2.4 Accountability & Inventory Control

As plant dealing with 3000 product variants as of now, huge amount of money involved in the business. So the organization needs to focus constantly on the accountability of these parts. Keeping right qty of material in stock for respective variants will make the work easier. For that it requires lots of time & money, for making this activity easier while designing the material handling unit standard we focused on two major things called primary & secondary material handling unit standard. In primary standard we focused on the internal material handling unit size, qty, strength of the material handling unit material & ensure that should be feasible for line issue. & create the warehouse more visible. Tagging instruction has been given for both to identify each material from the outer part of the material handling unit itself.

4.2.5 Shop floor strategy

While designing the material handling units also focused on the material requirement or past demand by line & found that material required by line in the multiple of 100 every time so keeping this in mind design of material handling units & primary packing & secondary packing has been decided. It helps supervisors & workers both to store, issue

& return of material & bulky storage avoided. It also helps the line people to reduce or eliminate on the line storage.

4.2.6 5S & Visual Management

Keeping in mind of 5S implementation & makes the store more visually better the MHUs has been designed. However at initial implementation phase first 3S are given priority for implementation. Also it will help workmen to keep the material into the racks & pallets easily & ensure the complete uses of storage space of rack & pallets. It also helps to understand the store more easily & about the location of each part inside the store. Also the material handling units are designed similar size & shape makes the store more unique. It also helps SAP to feed standard material handling unit into the system which saves a lot of time for accountability & location identification.

4.2.7 Manual Material Handling (MMH)

According to the U.S. Department of Labor, handling is defined as: Seizing, holding, grasping, turning, or otherwise working with the hand or hands. Fingers are involved only to the extent that they are an extension of the hand, such as to turn a switch or to shift automobile gears. In this publication, handling means that the worker's hands move individual containers manually by lifting, lowering, filling, emptying, or carrying them.

Manual material handling tasks may expose workers to physical risk factors. If these tasks are performed repeatedly or over long periods of time, they can lead to fatigue and injury. The main risk factors, or conditions, associated with the development of injuries in manual material handling tasks include:

- Awkward postures (e.g., bending, twisting)
- Repetitive motions (e.g., frequent reaching, lifting, carrying)
- Forceful exertions (e.g., carrying or lifting heavy loads)
- Pressure points (e.g., grasping [or contact from] loads, leaning against parts or surfaces that are hard or have sharp edges)
- Static postures (e.g., maintaining fixed positions for a long time)

Repeated or continual exposure to one or more of these factors initially may lead to fatigue and discomfort. Over time, injury to the back, shoulders, hands, wrists, or other parts of the body may occur. Injuries may include damage to muscles, tendons, ligaments, nerves, and blood vessels. Injuries of this type are known as musculoskeletal disorders. In addition, poor environmental conditions, such as extreme heat, cold, noise, and poor lighting, may increase workers' chances of developing other types of problems.

4.3 Value Stream Design of Proposed Handling Processes

Fig. 4.3.1

4.4 Implementation with new standard & Results

The proposed designed implemented in this case organization ABC Ltd.

The following action plans were made for this work.

- Identify problems in store with respect to packaging of BOP
- Analyze problems to find out the root cause
- Redesign & find out the new material handling unit standard to improve ROP & to reduce COPQ
- Give suggestions to increase work efficiency of workers

PROCESS ACTIVITY MAPPING		Time (Min)	Man Power	Operation	Transport	Inspect	Store	Delay

TOTAL		101						
OPERATORS			8					
% Improvement		56%	43%					

Fig. 4.4.1

The results obtained from the calculations

- Material handling unit designed for 7 out station suppliers for different parts
- New material handling unit standard implemented at 5 key suppliers end
- Communicated to remaining suppliers & to be implement by end of next year
- Dedicated storage area created, helped to keep material in standardized way
- Visual identification done throughout in house store
- Handling & ergonomically designed work area reduced worker fatigue
- Material handling trolley designed for material movement between store & production line to reduce effort of workmen
- All unorganized storage outside store eliminated after implementation of dedicated storage area
- Cost of poor quality (COPQ) reduced & Respect of product (ROP) improved
- Visual control of store improved & part searching time reduced
- Work pressure reduced for workmen, supervisor & improve stock keeping process
- Reduce Material handling casual from 14 to 8
- Delivery time reduced & material loading/unloading time reduced in case of industrial components from 60 mins to 8 mins

5. FUTURE SCOPE AND LIMITATIONS OF STUDY

Future Scope of the research work is given below:

- Development of kanban system for efficient communication between store and production line should takes place
- Value stream mapping for material store & issue process in order to identify and eliminate the non-value adding activities & eliminate uncertain line stoppage
- Stock level to be define to maintain correct stock level & avoid excess storage
- Receiving Inspection can be done on line to avoid multiple handling of goods

Limitations of the Study:

- Continuous follow up required for implementing the correct standard of material handling unit
- May required commercial discussion with supplier & required negotiation process
- May some of suppliers demand monetary help or cost addition to implement the new material handling unit standard
- New component addition may create confusion to decide standard material handling unit for suppliers
- May supplier will not ready to implement immediately

- May create dissatisfaction at supplier end

6. CONCLUSION

As per as the deliverables of the research work is concerned, with proposed design to optimize the time by more than 56% in material handling process& help to the organization to eliminate customer complaints by 50% . Every material comes in has its standard material handling unit & all material will reach to factory in safer & better condition. So advantages of proposed material handling process solution are

- Helps to eliminate loading and unloading activity
- Reduce effort of manual material handling activity
- Effective utilization of manpower available
- Reduce man power by 43% in case of manual material handling
- Visual management becomes better
- Reduce time in material handling process

LOGISTICS AND SUPPLY CHAIN MANAGEMENT

Six Sigma Approach for Reduction of Vehicle In-Vehicle Out (VIVO) Hours of the Outbound Logistics of a Steel Processing Industry

Shreya¹, Nitesh Jaiswal², Rajeev Agrawal³

^{1,3}Department of Production Engineering

Birla Institute of Technology, Mesra, Jharkhand, India.

² West Bokaro division Tata Steel, Jamshedpur, Jharkhand, India

Abstract: This paper explicates Six Sigma approach undertaken in a Steel Processing Industry to alleviate the Vehicle In Vehicle Out (VIVO) hours of the outbound logistics in the industry.

The research paper presents Six Sigma approach through five different phases: Define, Measure, Analyze, Improve, Control (DMAIC) in outbound logistics which has not been done significantly in this area. The application of DMAIC to the outbound logistics has given solutions to the problems incurred due to sudden rush of vehicles at a time due to customer urgency when the finished goods were not ready, material under hold due to quality check, delay in Delivery Order credit check and material under packing when the vehicle was waiting for loading. Further, the normal VIVO in outbound logistics improved from 61% to 80% thereby enhancing Sigma level from 2.676 to 4.142. Moreover Defects Per Million Opportunities (DPMO) decreased from 119703 to 4127 within one month. The paper presents a successful implementation of Six Sigma approach to reduce VIVO time and propounds for assessing progress to researchers and practitioners in the domain of Supply Chain Management in steel processing industry.

Keywords: Six Sigma, DMAIC, VIVO Hours, Outbound Logistics, DPMO, Supply Chain Management, Supply Chain.

1. INTRODUCTION

Logistics is an efficient management of the flow of products including storage in a supply chain. It is used to plan and coordinate the movement of products timely, safely and effectively. The most effective supply chains deliver products as fast and as cheaply as possible without sacrificing quality (Ballou, 1997). A manufacturing company generally has two kinds of logistics: Inbound Logistics, which brings in all raw materials, semi-finished goods, packaging materials to the industry and Outbound Logistics: which takes out all the finished goods from the company to distributors, dealers or retailers (Parwani and Jagadeesh, 2013). Regardless of the distance, each customer expects their products to be delivered quickly and flawlessly. In order to do this smart business there are various factors considered to align the pattern of movement of products in the most convenient and practical way. One such factor is VIVO time. VIVO time is the gate entry time to exit time for an inbound or outbound vehicle. High VIVO time is a cause of dissatisfaction for elite customers as transporters have to wait for long hours inside the plant and delivery to actual customers also get delayed. This is one of the challenges a steel processing industry confronts in the age of globalization. Steel processing industries are major suppliers to automobile industries. Automobile sales have been enlarging for several years and in today's

competitive scenario the automobile companies expect their suppliers to timely deliver the quality products. And VIVO time is the most important factor that determines the rating of the supplier companies like steel processing industries. The key to sustainable turnaround lies in how steel industry faces these challenges and develops combative and anticipatory process. The problem of high VIVO time was resolved by the application of Six-Sigma in outbound logistics as discussed in this paper which aims at reducing the VIVO time by greatly eliminating the negative effects of variation in the processes. It is imperative that the outbound logistics system of a company works efficiently to ensure that the goods reach destination at earliest possible time. This in return ensures meeting the demands at the destination points and leads to increased sales and in long run strengthens customer's loyalty.

The research work follows DMAIC methodology (Agrawal, Singh and Tiwary, 2017) of Six Sigma and there are various six sigma tools used in different phase of carrying out this research work, which are Supplies-Input-Process-Output-Customers (SIPOC) Chart (Mahendru and Singh, 2015), Project Charter, Process map, Capability analysis, Pareto chart, fishbone diagram, Normality Test Multi-Vari chart, Statistical process control (SPC) and Control Plan. This research work is divided into five phases (Define, Measure, Analyze, Improve and Control) which makes the research

work systematic and at the same time easy to accomplish the final goal. In Define phase the company's process was understood, the problem was identified and improvement opportunity is defined by background information to systematically support the project. In measure phase the variation in the data was measured and after narrowing down to certain reasons due to which inappropriate VIVO hours were occurring, the analysis was done in several brain storming sessions with analytical tools(Jadhav, 2013) to detect possible variations in loading of products and corresponding root causes were generated(Agrawal, Singh and Tiwary, 2017). Then in improve phase the process performance was improved by addressing root causes, discussing the alternative ways to counter the problems and accordingly action plans were proposed, henceforth controlling the improved process and future performance.

The brief detail of Six Sigma research work:

2. DEFINE PHASE

2.1 Problem Statement

In the steel Processing company where this research was carried out, vehicles (outbound – which are to be loaded with finished goods and sent out) took approximately 5-8 hours on an average from the point of entry through plant gate and exit. Such high VIVO hours were a cause of dissatisfaction for elite customers as transporters had to wait for long hours inside the plant and delivery to actual customers also got delayed. Due to such VIVO timing transporters had to keep their vehicle engaged inside the plant which was ultimately impacting their relationships too with other customers due to unavailability of vehicle.

So there was a need of reduction in average VIVO time. The goal of this research work was to reduce average VIVO time by 25 % minimum from the current level to deliver high service level to customer, enhance customer and stakeholder satisfaction.

The expected benefit from the successful implementation of Six Sigma were improved On Time In Full (OTIF)% (Szozda, Wojciechowska, 2011), increase in customer

satisfaction, improved stakeholder (transporter satisfaction) and enhanced morale of the drivers.

2.2 Process flow chart (VIVO Loading):-

As shown in figure 1, the process flow chart of outbound logistics was drawn to define the current state of workflow in outbound logistics and to study the process for improvement.

Fig. 1. Process Flow Chart of Outbound Logistics of the plant.

Process flowchart described a general mind-set to a step by step sketch for showing the process of outbound logistics from empty truck reporting at security gate to the loaded truck moving out of the security gate, but a detailed and focused diagram on the particular area of Outbound Logistics was needed. Hence SIPOC was drawn. As shown in Fig 2, SIPOC diagram along with Process flow diagram was established which summarised the whole process to define the outbound VIVO process clearly.

Fig. 2. SIPOC diagram with process flow diagram

The key metric which was used to evaluate the success of the research work were: DPMO (defects per million opportunities), % defects and sigma level. SIPOC Diagram with process flow diagram was established which summarised the whole

3. MEASURE PHASE

As shown in Table I, Data collection was done on each and every step of vehicle entry to Vehicle out to measure the current performance level of the outbound VIVO process.

TABLE I: Data Collection on each step

Measurement matrix	X or Y	Operation Definition	Type of data Discrete/Continuous	When will data be collected
Vehicle in Vehicle Out Time	Y	The clock time Vehicle is taken in by Security person at the Main Security Gate till the time vehicle is loaded and invoiced and leaves the Main gate	Continuous	In all shifts
Exact time at which vehicle is taken for loading (Tare weight recording)	X1	clock time between the tare weight in loading minus veh entry time recorded by security	Continuous	In all shifts
Time taken for loading	X2	Clock time between the gross weight recorded at weigh bridge minus the time at which tare weight was recorded	Continuous	In all shifts
Time taken for Invoice creation & printing	X3	Time taken for generating SAP Invoice & printing after the gross weight is taken	Continuous	In all shifts
LR Copy preparation by Transporter and security checks and outward of vehicle	X4	LR copy created by transporter minus the clock time at which the Invoice was handed over	Continuous	In all shifts

Thenormality of 6 months data collected was checked through Anderson-Darling Normality test(Anderson, 2010) to determine if data set is well-modeled by a normal distribution and to compute it for further analysis.

The outcome of the normality test is shown in Fig3, 4.

Fig. 3.: Normality Test

Process Sigma Level Calculator - Continuous Data (Assumes that data are normally distributed)			
Sample Data (user inputs):			
Mean	x-bar		5.6
Standard Deviation	s		0.34
Upper Specification Limit	USL		6
Lower Specification Limit	LSL		3
Sigma Shift (typically +1.5 for long term data)			1.5
Results:			
Expected dpm > USL			119703.4
Expected % > USL			11.97%
Expected dpm < LSL			0.0
Expected % < LSL			0.00%
Expected dpm (overall)			119703.4
Expected yield (overall) %			88.03%
Process Sigma Level			2.676

Fig. 4. Process Sigma Level

Since p value is greater than 0.5 the data is normal. Then after the further calculation was carried out on the data. Sigma Level was calculated before implementing DMAIC model and the value was 2.676 and DPMO (Defect per Million Opportunity) was 119703.4

4. ANALYSIS PHASE

This phase is the most important to find the causes of mostly changing the process by identifying the bottlenecks of the process and henceforth digging out the sub causes of the problems(Patil et al, 2015).

4.1 Analysis on Sample data

Pareto Analysis was done on the 6 months data (Fig 6). It

was observed that out of 17 reasons responsible for long vivo hours, 5 of the reasons contributed to 80% of the long VIVO hours.

Fig. 5. Pareto Chart of Past data

The major reasons which caused high VIVO time were Material under process, Material under packing or packing not done and Deliver order credit check delay.

After selecting the bottlenecks with higher frequency that led to high VIVO time, rigorous brainstorming in the why-why sessions cause and effects diagram for all the bottlenecks were highlighted, all of these factors are summarized in the fishbone diagram in Fig. 9, 10, 11. The parameters considered were: Man, Method, Material, Machine, Customer and Transporter. Moreover the sub causes to the causes generated were also found.

- CAUSE AND EFFECT DIAGRAM OF material Under Process & DO credit Check was drawn (SEE fig 9, 10)

Fig. 7. Cause and effect diagram

- CAUSE AND EFFECT DIAGRAM OF material Under Packing (see fig 11)

Fig. 6. Cause and effect diagram.

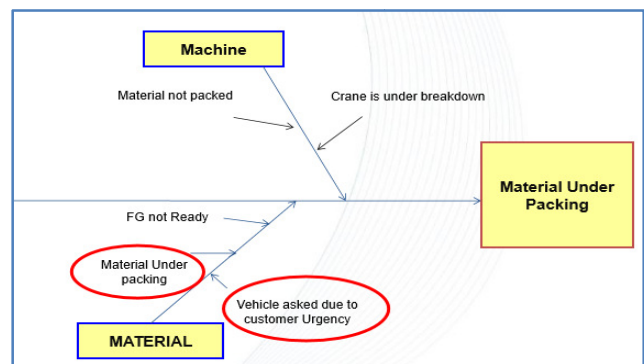

Fig. 8. Cause and effect diagram.

The major sub causes which led to the high VIVO time is marked red in the fish bone diagram.

The team had a detailed discussion in this regard with the engineers, the operators and supervisors in charge. Based on this discussion, an action plan was prepared with details of data on each cause and the type of validation required.

5. IMPROVE PHASE

This phase statistically reviewed the variations in the process and determined what factors significantly contribute to the output (Patil et al, 2015). The main goal of this Improve phase was to develop optimal solutions of the problems henceforth the Action Plan was made ready to reach the goal as shown in Table II.

TABLE II: Action Plan for improvement of outbound logistics.

SN	Major Reasons for High VIVO hours	Root cause	Responsibility	ACTION PLAN
1	Credit check/ DO not released for Customers	Due to same day planning of vehicle DO's are not released as per dispatch plan	Logistics Team	1 day advanced despatch plan will be done, DO will be released same day and vehicle will be placed second day.
2	Material under process	Due to Vehicle Placed prior to FG ready vehicle waiting time increased	Logistics Team	Despatch plan will be done purely on FG availability, vehicle will be placed after FG
3	Vehicle waiting in queue	Due to Multiple loading points vehicle wait in queue parking area	Despatch Team	FIFO system will be followed and from now onwards if FG will be ready in advance vehicle waiting time will be reduced
4	Packing not done	Due to Material showing FG in system & Physically materials packaging is pending.	Despatch team, Packaging contractor & Production	to be discussed with Production and Packaging contractor for packaging lead time finalization

- **Material Under Process:** Earlier higher outbound vehicles delayed due to Material under process. Then the action taken was that the Vehicle planning will be done after material will be ready as Finished good.
- **Loading point busy** –Earlier vehicle used to wait in a queue but then the action taken was that the FIFO system would be followed.
- Earlier there used to be delay due to Delivery Order credit check. But then the action taken was: Vehicle will not be allowed to enter In the plant without advance delivery order or credit order.
- **Material NOT FOUND** was another reason for higher VIVO hours so the action taken was that the Auto Delivery system was installed. It resulted in reduction of Invoicing Delay and Material not found delay.
- Cold Rolled and Hot Rolled Finished Goods packets were arranged Material Thickness wise. This helped to reduce the Material Searching time.
- There were several cases of Packing not done so the action taken was that a 2.5 Mt small crane was installed in the CR plant to improve the Packaging speed for Narrow coils.

After the attainment of these improvement actions, Defects per million and sigma level were calculated. The process

showed the sigma level rise of 2.4 in Cold Rolled plant's outbound logistics and 1.46 sigma level rise in Hot Rolled plant's outbound logistics.

6. CONTROL PHASE

One month after the containment action % defect, DPMO and Sigma Level of the complete VIVO process were calculated to measure the overall improvement of the process (Agrawal, Singh and Tiwary, 2017) (Table III).

TABLE III: Sigma Level comparison before and after.

Metric	Before	After
% Defect	11.97%	.41%
DPMO	119703	4127
Sigma level	2.676	4.142

The major problems for the inappropriate VIVO hours were analyzed and corrective actions were taken. The correct VIVO time improved from 61% to 80%. Sigma level rose from 2.676 to 4.142. Such rise in sigma level is quite beneficial for the company.

Process Sigma level calculation of the continuous data is shown in figure 12.

Before			After		
Process Sigma Level Calculator - Continuous Data (Assumes that data are normally distributed)			Process Sigma Level Calculator - Continuous Data (Assumes that data are normally distributed)		
Sample Data (user inputs):			Sample Data (user inputs):

Process Sigma Level		2.676	Process Sigma Level		4.142

Fig. 9. VIVO Process Sigma level calculation

7. CONCLUSION

The variation reduction and reduction of defects are critical to the logistician by managing inventory, customer's trust and smooth movement of goods timely. This research work proposes the 'VIVO Hours Analysis Of Outbound Logistics' in a steel processing industry. A detailed process map was drawn and the bottlenecks in the smooth flow of the process were identified. A pareto chart was drawn to find out which were the major reasons leading to inappropriate VIVO hours. They were identified as material under process, material under packing or packing not done, deliver order credit check delay and loading point busy. Then after fishbone diagram(Rumana and Desai, 2014) was drawn to find the causes for these effects and subcauses were identified. Then further analysis of each potential root causes were conducted using a lot of brainstorming sessions. For each cause, emendation was provided. The action plan was designed and improvements were implemented. The potential benefits from the chosen solutions were evident from the very next day. (Mijajlevski, 2013)

The correctedVIVO rose from 61% to 80% and Sigma level enhanced from 2.676 to 4.142 in one month. Such rise in sigma level is lucrative for the company.

Abstract: The ever increasing requirement of providing better services in hospitals at reasonable cost, in least possible time has made to proactively think towards identify and prioritise the areas of concern, which can integrate all business operations of hospital. To accomplish this, supply chain management (SCM) has role to play in reducing cost, time and improving the performance in hospital operations and thereby enabling the hospital supply chain for continual improvement. In order to address the issue of performance measurement of hospital supply chain, one must consider hospital supply chain efficiency. This paper reviews briefly the existing literature on hospital supply chain performance measurement. & identify the challenges of hospital supply chain management and potential performance measure to evaluate the performance of hospital supply chain. Identification and prioritization needs proper framework to categories the constructs. Hence, the objective of the paper is to present conceptual framework considering the supply chain efficiency parameters with various attributes and hospital supply chain components (Medical Treatment Operation & Supporting/ Allied Operations). The framework is proposed to prioritize various performance metrics identified from literature review.

Keywords: Supply ChainManagement, Hospital Supply Chain, Healthcare supply chain, Performance Measures, Analytical Hierarchy Process

1. INTRODUCTION

The philosophy of supply chain management has been adopted to supervise various operation/ activities over longer period of time. In order to be assured of successful supply chain management adoption, performance measurement is very important. Performance measurement is a tool to monitor the efficiency and effectiveness of operation being carried out [Kumar et al., 2005; Neely et al., 1996]. Supply chain performance measurement must consider whole supply chain perspective. It can be done by considering business operation carried out in particular supply chain. Performance measurement of supply chain must be done to enhance the effectiveness and efficiency of supply chain as a whole [Beamon, 1999]. Few work present the development of performance measurement framework in hospital, whereas they lack in considering hospital supply chain aspect[Berenson et al., 2013; Bititci et al., 2010]. While other studies focuses on the measurement and improvement of particular business operation in hospital supply chain [da Encarnação et al., 2009; Elg et al., 2013]. There are very limited number of studies which explored the hospital supply chain performance measurement as a whole [Lorden et al., 2008; Purbey et al., 2007]. This paper proposes a conceptual hierarchical framework for prioritizing performance measures. Proposed framework considers the supply chain efficiency dimensions as criteria

and hospital supply chain operation as alternatives to monitor the performance.

The rest of the paper is presented in 6 sections; section 2 covers an overview of work done on hospital supply chain performance measurement, section 3 elaborates the various operations/ activities/ processes of hospital supply chain, section 4 presents performance measurement criteria for hospital supply chain and associated sub-criteria. Proposed conceptual framework and prioritization of performance measures will be presented in section 5, section 6 concludes the study followed by section 7 of reference.

2. OBJECTIVE OF PROPOSED CONCEPTUAL STUDY

Hospital supply chain is constantly going through challenges and opportunities resulting due to ever dynamic operation conditions which consist of expectations of service quality of healthcare at affordable cost. Concurrent improvement in quality and efficiency leads to make customer demands more expensive. Measuring the performance can enable the healthcare professionals to assess the improvement in activities towards attainment of strategic goals and objective of the hospital. Adoption of appropriate performance measures/ metrics plays most important role in highlighting the efficiency of healthcare supply chain performance measurement. The selection of these performance measures widely considers the benefits of

hospitals, clinicians and customers(patients). These will help in raising the service value of healthcare supply chain management/. During literature review related to supply chain performance measurement of hospital supply chain, we came across various measures such as healthcare services, communication, patient safety, waiting times, and integration, which affects the supply chain management. Whereas, cost and time are the most important criteria of today's hospital supply chain.

Along with this, reliability of utilized healthcare services and productivity of medical treatment processes is also an vital criteria for today's hospital supply chain. Together, if we consider the aspects of cost, time, reliability and productivity of supply chain, they becomes the construct of supply chain efficiency. Therefore, improving overall supply chain efficiency with high level of service quality is major context for enhancing hospital supply chain performance. Besides this, in order to recognize the processes of hospital supply chain for successful management of supply chain, therefore must look at both operation of hospital supply chain i.e medical treatment operation and supporting/ allied operations. The sole objective of this study is to provide and an brief overview on performance measurement of hospital supply chain. More precisely, the purpose of this study is to;

- i. To identify the performance measures for constructs under supply chain efficiency for hospital supply chain.
- ii. To proposed a conceptual hierarchial performance measurement framework for hospital supply chain considering supply chain efficiency drivers and hospital supply chain operations.

3. OVERVIEW OF LITERATURE ON SUPPLY CHAIN PERFORMANCE MEASUREMENT IN HOSPITALS

3.1 Brief Overview of Performance Measurement System

Performance measurement facilitates guidance, and improvement action in various conditions depending on the contextual utility and application (Elg et al, 2013). Further, the concept of performance measurement system is predominantly applied in public reporting, provider incentive programs and also in quality improvement programs (Berenson et al, 2013). Performance measurement system are conceptualized in various ways such as "organizational performance assessment system", outcome based management system" etc. Several definition were introduced in the literature by various authors exhibiting its application areas in an attempt to resolve this complexity of performance measurement system.

3.2 Performance Measurement System for Healthcare Supply chain Management

Globally, there is an intense complexities in healthcare systems. Owing to which, healthcare service providers are challenged to provide efficient services at affordable cost. Hence, healthcare performance measurement becomes very important, specially considering the overall activities of the hospital supply chain management. It becomes important to recognize the supply chain management components in hospital, which can be considered for continuous improvement leading to improved service quality and safety. Elements of supply chain management for hospital consist of medical treatment unit, supporting units and hospital storage treated as internal supply chain(Supeekit et al, 2015), whereas, externally chain includes vendors, manufacturers and distributors etc. The prime concentration of healthcare supply chain management relies on its performance assessment. The ultimate aspect for healthcare supply chain is safety and satisfaction of the patient.

Healthcare supply chain is very complex yet unexplored. There are multiple reasons for healthcare supply chain management to be immature which can be less management involvement, redundancy in clinical processes, etc. Also, cost has major impact in healthcare supply chain(Kumar et al, 2008). Constraint of time plays vital role while considering the safety of the patient. It has been evident that, there is very less studies explored the potential of hospital supply chain an internal chain. Hence, paper projected to consider the hospital supply chain with an approach of proposing a framework for performance measurement of supply chain. Here, we would be considering the subsets of internal supply chain such as medical treatment operation and supporting/allied operations. Success of any supply chain lies in improving its efficiency(Supeekit et al, 2015). Therefore, we suggest to consider the construct of supply chain efficiency with hospital supply chain operation to design a framework.

4. HOSPITAL SUPPLY CHAIN OPERATION

Hospital supply chain in this study is shown in figure 1. It is one of the most complex supply chains. End user of hospital supply chain is patients who seek diagnosis and pursue the treatment (Dobrzykowski et al, 2009). For achieving the satisfaction of patients (customers), both medical treatment (services from medical professionals) and supporting operations (pharmaceutical and medical supplies) are equally important (Parnaby et al 2009 & Singh, 2008). In order to improve the efficiency of hospital supply chain performance for successful management of the supply chain, it is important to explore various activities under major hospital supply chain operation i.e. medical care and supporting operations, which are as given below;

Fig. 1. Hospital Supply chain

A. Medical Treatment Operations

Medical treatment operations facilitate medical overhaul to patients (customers). Main resources for this operation are doctors, nurses; whereas medical tools and equipment are integral part while treating to patients. There are various places where medical treatments are done such as Surgery, Neurology and Pediatrics etc. Medical treatment activities as cited in literature (Bhattacharjee et al, 2014 & Kujala, 2006 & Rahimnia et al, 2010) are as follows;

- i) **Admittance:** - Most initial activity, various stages are there is this activity for patients to be cared and treated. Stages such as registration, triage, and inpatient admission.
- ii) **Patient Examination:** - In order to be treated properly and to get cured as early as possible, patient's examination is done by nurses and doctors.
- iii) **Treatment Delivery:** - Post examination, mode and pattern of treatment is decided. Treatment can be of short span/ long term depending on the nature of patient's disease.
- iv) **Discharge/Transfer:** -Preferably the last stage at any hospital. This is done in either cases, when patient is treated and cured or when patient's criticality is not in reach of particular hospital expertise.

B. Supporting/ Allied Operations

Supporting operation adds value to medical treatment processes. In order to examine, treat and cure patient, clinical materials such as pharmaceutical, medical supplies, and medical equipment are required. These processes normally occur into two major units: medical supporting units (Singh 2008, Swinehart et al, 2005 & Narayana et al, 2014 & Mustaffa et al, 2009) such as radiology, laboratory and pharmacy; and non-medical supporting units (Kumar et al 2005, 2008 & Singh 2008) such as porting service for patient, supply & demand management, and sterilized services. The supporting processes involve the following processes.

- i) **Supply & Demand Management:** - This includes procurement of medical materials from various suppliers or supporting units when needed.
- ii) **Synthesis:** - This includes the preparation of medical treatment materials for clinical operations.
- iii) **Movement:** - This includes transfer of materials or patient to the point of care or where the materials or patients are required to be treated.
- iv) **Stock & Capacity Management:** - This include the processes to ensure the availability of medical materials while keeping the cost lowest possible and also it ensures the resource management in the hospital to avoid wait/ delays.

5. HOSPITAL SUPPLY CHAIN PERFORMANCE

Performance measurement is a process which provides strategic decision making for improvements in firm/ organization. In order to observe improvement in a supply chain, the initiatives for performance measurement must be supply chain centric so as to enhance supply chain efficiency (Beamon 1999 & Cai 2009 & Gunasekaran et al 2004, 2007). Hence, hospital supply chain performance measurement must ensure the involvement of supply chain efficiency in medical treatment and supporting operation. Studies revealed that, (Barnabè 2011 & Battini 2009) patient safety primarily be the most important concern to ensure best possible service to patient. In order to ensure patient safety, the supply chain performance measurement system for the hospital supply chain should consider the supply chain efficiency constructs as the criteria with various sub-criteria contribution to overall supply chain performance for hospital. Furthermore, the performance measurement system must possess a unambiguous justification of criteria and a relationship model between criteria, sub-criteria and alternative on which performance of supply chain is to be evaluated (Cai 2009 & Berrah et al 2007). This section would explore the hospital supply chain performance criteria including supply chain efficiency criteria.

5.1 Supply Chain Efficiency: -

Supply chain efficiency takes into consideration of multiple performance criteria linked to supply chain operations with integration of supply chain partners (Aronovich 2010 & Pettersson 2008). The most important criteria which are considered while thinking of supply chain efficiency include cost & time (Goedhals 2010 & Pettersson 2008), whereas with respect to supply chain context reliability received lot of attention. In addition, so as to measure the efficient use of resources, productivity has also gained lot of importance (Pettersson 2008). Therefore, supply chain efficiency with four dimensions for this study is as follows;

- i. Cost- Managing Cost effectively and efficiently
- ii. Time- Managing Time of all operations with high responsiveness
- iii. Reliability- Ensuring the accuracy of the treatment processes and its sustainability.
- iv. Productivity- Ensuring optimum utilization of resources available to carry out medical treatment processes.

6. CONCEPTUAL FRAMEWORK FOR HOSPITAL SUPPLY CHAIN PERFORMANCE MEASUREMENT

This section presents the conceptual framework for measuring hospital supply chain performance measurement. As discusses earlier, framework is conceptual and presented based on brief overview of available literature pertaining to healthcare supply chain management, more precisely

hospital supply chain. The need of the hospital supply chain management is studied. Four constructs for supply chain efficiency is considered, which are; cost, time, reliability and productivity as discusses earlier. In order, to gauge the performance more accurately, various performance measures were identified from literature and categorized as per their characteristics under these constructs of supply chain efficiency. The various performance measures are as shown in table 1. Performance measures identified from literature review list in the table probably may not be all are equally relevant and critical to assess the hospital supply chain performance. Hence, the purpose of this study is to present a framework to prioritize them and rank as per their level of contribution towards supply chain performance in hospital supply chain.

The framework also consist of areas where these criteria and sub-criteria would affect, and they are the compoenet of hospital supply chain management (Medical Treatment Operation & Supporting/ Allied Operation).

The proposed framework is composed of following elements;

Overall Goal: - Hospital Supply Chain Performance

Criteria: - Medical Treatment Operations, Supporting/ Allied Opertaion (Compoenents of Hospital Supply Chain Management)

Sub-criteria: - Total 50 performance measures grouped under components and categorized based on their nature.

Alternatives: - Supply Chain Efficiency Constructs (Cost, Time, Reliability, Productivity & Safety)

TABLE 1: Performance Measures for components of hospital supply chain categorized under four criteria

Sr. No.	Performance Criteria	Components of Hospital Supply Chain Management	
		Medical Treatment Operation(22)	Supporting/ Allied Operation(28)
1	Cost	i. Cost of Inspection ii. Cost of Capital resources iii. Cost of Care iv. Operating Cost	i. Cost to issue orders ii. Total cost of supplies iii. Inventory days of supply iv. Value of buffer stock v. Revenue per Physician
2	Time	i. Time to Admit ii. Patient waiting time iii. Response Time to Unplanned Issue iv. Time to discharge v. Patient Turnaround time	i. Sourcing Response Time ii. Order Lead time iii. Order processing Time iv. Order fulfillment cycle time v. Production/ Preparation Time vi. Transportation Time vii. Cycle Time for
3	Reliability	i. Accessibility ii. Accuracy of Results iii. Accuracy of Medical Treatment iv. Accuracy of Discharge Process	i. Lead Time Variability ii. Fill Rate iii. Percentage of Rush Orders iv. Accuracy of Orders

Sr. No.	Performance Criteria	Components of Hospital Supply Chain Management	
		Medical Treatment Operation(22)	Supporting/ Allied Operation(28)
			v. Stock out at point of Use vi. Stock Accuracy vii. Pick & Pack Accuracy viii. On Time Delivery ix. Response Time to Urgent Request
4	Productivity	i. Availability of Tool ii. Productivity of Testing Lab iii. Productivity of Doctors iv. Productivity of Support Staff (Nurses) v. Resource Utilization vi. Bed Turnover	i. Inventory Tunover ii. Availability of Tools/ equipments iii. Staff Productivity iv. Availability of Porters
5	Safety	i. Technical Quality of Care ii. Communication/Information iii. Caring/Compassion	i. Authentication of Medical Suppliers ii. Handling of Clinical Material iii. Availability of Phamaceutical materials.

Fig. 2. Hierarchical Representation of the Framework for assessing hospital supply chain performance

7. CONCLUSION

The ultimate objective of the the study identify and prioritise critical performance measures used to assess the performance of hospital supply chain management In order, to undertake this study, brief overview of literature is done and it is evident from it, that, very scare studies are being conducted in the field of supply chain performance mearuement in the healthcare sector of india specially for hospital supply chain. Study identified that there are two parts of healthcare supply chain management, internal chain (hospital supply chain) and external chain (consist of vendors, manufactures and distributors of medical supply

supplies(pharmaceuticals and devices)). Focus of this study is concentrated on hospital supply chain management. A framework is suggested comprising of goal as overall supply chain performance, with criteria supply chain efficiency constructs i.e. Cost, Time, Reliability, Productivity & Safety with almost 50 sub-criteria or performance measures categorized under them collectively. Whereas these performance constructs and sub-criteria will be prioritised on components of hospital supply chain management i.e., Medical Treatment Operation and Supporting/ Allied Operations. The Paper presented here, proposes conceptual framework for assessing hospital supply chain performance. However, the study will follow

with prioritization and ranking of critical performance measures for hospital supply chain.

Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

Abstract: The aim of this research is to study the various green supply chain management enablers (GSCMEs) and build awareness about these GSCMEs. The nationwide survey of Indian automobile organizations has been conducted to check the status of GSCMEs for successful GSCM implementation. The result shows that top management commitment and support, supplier commitment, environmental policy, strategic planning and GSCM methodology are five most important GSCMEs. The outcomes of this study have provided substantial and innovative information by signifying several criteria and a simple, efficient method through which decision makers can improve their capability to analyze the GSCMEs for successful GSCM implementation. In addition, the ranking tactics of GSCM implementation show the respondent's observations about the significance of them and helped organizations to identify their strengths to move towards continuous improvement.

Keywords: GSCM, enabler, survey

1. INTRODUCTION

The environmental concerns have prompted people from all domains of the society to take a more energetic stand for the advancement and execution of practices that can help businesses reduce their negative impact on the environment [Sarmiento and Thomas, 2010]. Organizational requirement helps in highlighting the relationship among sustainability and performance and focuses on assessing the economic, environmental and social impacts on their activities [Subramanian, and Gunasekaran, 2015]. As customers are becoming more environmentally conscious and governments are making stricter environmental regulations, the organizations need to reduce the environmental impact of their manufacturing activities [Mathiyazhagan et al., 2013]. Environmental management is an important issue in supply chain management (SCM) [Govindan et al., 2014]. For the success of environmental programs, the whole SC should go greener by implementing green supply chain management (GSCM). GSCM is the process of integrating environmental concerns into business accomplishments [Liou et al., 2016]. GSCM maximizes the global environmental profit by implementing a life cycle tactic through manufacturing, material selection, product design, and sales and recovery, and hence, supports the organization's to understand its sustainable growth and development [Shi et al., 2012]. GSCM promotes efficiency and synergy among business partners and their lead corporations [Madaan and Mangla, 2015]. The concept of GSCM is not new but there is no clear and perfect policy for GSCM implementation in the organizations. The GSCM

implementation requires identification of GSCM enablers (GSCMEs).

The aim of this research is to study the various GSCMEs and build awareness about these GSCMEs. The nationwide survey of Indian automobile organizations has been conducted to check the status of GSCMEs for successful GSCM implementation. Hence, a study of the GSCMEs of these surveyed organizations might offer a reasonable valuation for GSCM implementation for Indian automobile organizations. From literature review and experts discussion total 35 GSCMEs were selected for the analysis (see Table IV). This study is organized in four sections including introduction. Section II provides literature review about GSCMEs. Section III shows the methodology of survey and its analysis. Last section IV deals conclusion, limitations and future scope of the present study.

2. LITERATURE REVIEW

Many authors have researched and written directly on the GSCMEs. Most of the studies were emphasized on reduction, remanufacturing, recycling, product design, process plan, manufacturing practices, procurement, and some mixing of items across the managerial levels [Sarkis et al., 2011]. [Wang et al., 2016] develops a conceptual model with four hypotheses to propose moderation and mediation effects of customer relational governance (CRG) on the relationships between two GSCM practices (green innovation and green purchasing) and environmental/economic performance. Luthra et al., 2016 anticipated the overall organizational performance

outcomes by examining the impacts of critical success factors to implement GSCM towards sustainability by implementing green practices in Indian automobile industry. [Teixeira, 2015] analyzed the relationship between GSCM practices (green purchasing and collaboration with customers) and green training by presenting the empirical evidence from Brazilian firm. [Mohanty et al., 2012] presented an empirical study of GSCM practices in the Micro, small and medium enterprises (MSMEs) in India and revealed that Indian MSMEs face significant pressures from external stakeholders to adopt GSCM practices. [Muduli et al., 2013] identified twelve behavioral factors, which explore the various behavioral factors affecting GSCM practices, their interactions and help to attain green-enabled needs. [Diabat et al., 2013] focuses on ranking for GSCM practices and performances between organizations conducted in an automotive organization of a developing country. The results enable automobile manufacturing organizations to appraise their own strengths and weaknesses in implementing these practices.

[Zhu, 2012] empirically tested the theoretical relationships on the GSCM implementation. This study provides practical implications for manufacturers to identify ways for improving environmental and operational performance, as well as, economic benefits through proper design of GSCM practices. [Azevedo et al., 2011] examined the relationships among green practices of SCM and SC performance. The conceptual model provides evidence as to which green practices have a positive effect on quality, customer satisfaction and efficiency. [Holt, and A.Ghobadian, 2009] investigated the level and nature of greening the SC in the UK manufacturing sector. It also explored the driving forces behind environmental behavior, the specific management practices and the relationships among them. [Zhu and Sarkis, 2007] studied the moderating effect of institutional pressures on GSCM implementation exposed that organizations facing higher regulatory pressures tend to implement GSCM practices. [Lee, 2008] acknowledged the main drivers for organizations to contribute to the GSCM implementation as government involvement, buyer influence and GSCM willingness. [Kainuma, and Tawara, 2006] considered the extent of lean and GSCM practices. [Sheu et al., 2005] obtained seven critical factors in their research into environmental management namely total involvement of employees, green products/process design, top management commitment, training, measurement, information management and supplier management. [Wee, 2005] offered a combined

logistics operational model to manage the cross-functional product logistics flows and used-product reverse logistics flows in a given GSCM. The outcome of the proposed integrated logistics operational model helps to improve the chain-based aggregate net profits and the relative existing operational performance of the SC.

3. METHODOLOGY

A. Questionnaire survey

Instrument development

A structured questionnaire was framed to collect responses on a five-point Likert scale. On the scale, 1 stands for strongly disagree and 5 for strongly agree. The questionnaire had two sections and was designed to collect detailed information about-

- the profile of the respondents, organizations, objectives of GSCM [07 questions];
- GSCM enablers (GSCMEs) [01 Question];

Before sending the questionnaire to the organizations, a pilot study was carried. The ideas behind carrying out the pilot study were to obtain fruitful feedback from executives working in the area of GSCM, to add questions, if any, missing from the questionnaire, to delete any irrelevant questions, and to refine/rephrase the language of the existing questions to bring more clarity to the questionnaire. A total of six executives were personally contacted. Accordingly the questionnaire was modified and a final questionnaire was developed. It was then mailed to different organizations. Those executives suggested developing the subgroups among the identified GSCMEs for better understanding of the questionnaires.

Around 550 mails were sends to industries located in deferent part of the country. The total responses obtain from both online and offline are 131 which represent the response rate of 23.8%, which is satisfactory for such type of survey.

Sample characteristics of the respondents and organizations

Table I andII gives the demographic profile of the respondents (job title, job function, and years worked at the organization) and organizations participated (the primary production system, industry, employment size, profit etc.) in survey respectively.

TABLE I: Demographic Profile of Respondents (IN %)

Participants position level	Senior	Middle	Junior	
Managerial Level	12.9	47.3	39.7	

Educational qualification	Diploma	Bachelor's degree	Master's degree	Doctoral
	16.8	64.9	18.3	0

TABLE II: Demographic Profile of Organizations (IN %)

Sector	Public	Private	Government	Others	
	6.8	85.5	3.8	3.8	
Size	Large Scale	Medium scale	Small scale		
	58	32.1	9.9		
Number of employees	<100	101-500	501-1000	Over 1000	
	5.3	28.2	24.4	42	
Annual sales turnover	<5 Cr.	5-50 Cr.	51-100 Cr.	101-500 Cr.	Over 500 Cr.
	9.9	15.3	14.5	26	34.4

B. Annual sales turnover and trends in profit of the organizations

TABLE III gives the trends observed in the annual sales turnover and profits of these organizations during the last three years.

TABLE III: Trend in Annual Sales Turnover and Profits for the Last 3 Years (IN %)

	Increased up to 10%	Increased above 10 %	Constant	Decreased
Annual sales turnover	37.4	48.9	6.9	6.9
Profit/loss	33.6	35.9	26	4.6

C. Results of survey analysis

Reliability analysis of the questionnaires

The values of alphas (α) have been found to be more than 0.5 with an average of 0.92. It implies that there is a high degree of internal consistency in the responses to the questionnaire [Rungasamy et al., 2002; Nunnally, 1978; Nunnally and Bernstein, 1994].

Descriptive statistics of GSCMEs

The relevant descriptive statistics are shown in Table IV. Also the priority weight of 35enablers is calculated by dividing each GSCME by the sum of its columns (Table IV). However the mean values 35 GSCMEs were obtained and analysis has been done.

TABLE IV: Descriptive Statistics

Influencing Factors	Mean	SD	Rank
Top management commitment and support	4.32	0.77	1
Supplier commitment	4.15	0.94	2
Environmental policy	4.09	0.85	3

Influencing Factors	Mean	SD	Rank
Strategic planning	4.02	0.75	4
GSCM Methodology	3.96	0.86	5
Organizational structure	3.95	0.76	6
Willingness towards investment	3.92	0.82	7
Employee empowerment and motivation	3.91	0.92	8
Green organizational culture	3.88	0.93	9
Information technology infrastructure	3.87	0.76	10

Collaborative research & development with supplier	2.95	1.39	30
Customer awareness	2.94	1.27	31
Availability of new technology	2.94	1.39	32
Awareness about new technology	2.93	1.38	33
Environmental related programs and meetings	2.92	1.39	34
Supplier adoptability	2.87	1.22	35

4. CONCLUSION

The aim of this research is to study the various GSCMEs and build awareness about these GSCMEs. The nationwide survey of Indian automobile organizations has been conducted to check the status of GSCMEs for successful GSCM implementation. The result shows that Top management commitment and support (4.32), Supplier commitment (4.15), Environmental policy (4.09), Strategic

planning (4.02), GSCM Methodology (3.96) are five most important GSCMEs. These factors should consider more cautiously and in an effective way because these factors provides the complete basis for successful GSCM implementation. The survey approach may be useful to GSCM managers of an organization to employ this model to identify and classify the significant GSCMEs for their needs. This model also reveals the direct and indirect effect

on each enabler on the GSCM implementation. Once these GSCMEs are identified, the top management could formulate a strategy for enhancing their effects during GSCM implementation in automobile industries. Accordingly GSCM managers may also strategically plan its long-term growth strategy to meet GSCM action plan. The outcomes of this study have provided substantial and innovative information by signifying several criteria and a simple, efficient method through which decision makers can improve their capability to analyze the various GSCMEs for successful implementation of GSCM. In addition, the ranking tactics of GSCM implementation show the respondent's observations about the significance of them and helped organizations to identify their strengths to move towards continuous improvement. This study is limited in surveying the status of GSCMEs only in Indian automobile industries. Future study may conduct for some other type of industries in Indian context and in global context.

Postponement: A Theoretical View

Himanshu Prajapati, Ravi Kant

Department of Mechanical Engineering
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

Abstract: Modern Supply Chain is focused mainly towards customer perception in preparing a product. This requires flexibility towards manufacturing activities. Mass customization is a trend in which the benefit of mass production and product customization both are included. Modern manufacturing is based on the same. Postponement (PP) is a supply chain practice in which final activities in assembly of a product is not performed until customer order arrives. This paper highlights the concepts and perception towards PP. The benefits of adopting PP activities over traditional practices have also been listed. Theoretical analysis of literature is performed to find out the enablers and barriers towards implementation of PP activities. This supply chain activity is a need for the current market competition. This has to be associated with excellent forecasting techniques to remove uncertainty.

Keywords: Supply chain practices, Postponement,

1. INTRODUCTION

In the today's competitive world, companies are focused towards making customer specific products. Producers have developed many supply chain strategies and practices to concentrate on product procreation and meeting customer needs (Kisperska and Swierczek, 2011). Delayed product differentiation is a concept that has helped producers to reduce their inventory requirements and at the same time makes the availability of the product at gross.

Conventionally, mass production was the concept adopted by the companies to get volume benefit. This doesn't support PP activities. Whereas today new supply chain concepts put forward this concept to get a better market share (customers) instead of dumping products into the market. Undeniably, mass production targets large batch type production and benefits of product standardization and not on customization of product(s). Supply Chain Management (SCM), on the other hand, puts forth customer and their preferences thus expanding the purpose of PP.

Mixing the concept of mass production and production customization, companies use concept of mass customization wherein then final structure of the product is delayed to the last possible moment. Mass Customization provides marketing benefit of customization to the manufacturer while bringing in the profit of having standardized products in the outlook of future customer orders.

Postponement is a perception wherein some of the supply chain activities of the product are not performed until customer orders arrives (Van Hoek, 2001). The concept of PP arises because of the increase in demand of the customized products in the market (Kisperska and Swierczek, 2011). Postponement is a concept in SCM where

the manufacturer produces a conventional product, which can be modified at the later stages before the final transport to the customer. One of the classic examples of PP is of paint companies. All the paint companies were initially burdened with maintaining a number of shades (particularly above 150 shades) in inventory which was destroying the business. Later one company came up with a concept that they will produce only white paint and a number of shades can be prepared by mixing up different ratios of basic three colors. This was done at retailer level. When customer demands of a particular color, the retailer just has to mix a fix proportion of color in white paint with the help of a mixing machine. Thus the problem of maintaining inventories of different color bottle was solved. Another example is at the production facility of Dell computers. When booking computers online, Dell provides facility to personalize the computer according to the buyer need of specifications such as processor speed, ram requirement, hard disk size, software and other peripherals (Selladurai, 2004).

Companies facing a high extent of uncertainty, it is a choice of benefit to adopt PP activities. There are various ways to adopt for PP according to the requirement in a particular institution. First step is to reduce process uncertainty as companies get time to go for better manufacturing process and adopt a good transportation network. Second to reduce the uncertainties towards supplier side. Third step is to reduce demand uncertainties for practicing PP over the entire supply chain (Yang and Burn, 2003).

2. POSTPONEMENT: CONCEPTS AND PERCEPTION

The concept of PP is not a new concept. It has not only studied theoretically but is being in practice into industry since late 1950's (Kisperska and Swierczek, 2011). The

concept of PP dates back in late 1960's (Bucklin, 1965), but the main focus toward this turns into late 1990's when a number of papers was being published in various streams such as logistics, strategy operation research etc. (Pagh and Cooper, 1998, Feitzinger and Lee, 1997, Garg and Tang, 1997).

PP has been increased in use by the managers after 1995. It was predicted by Morehouse and Bowersox (1995) that by 2010 more than half of the inventory in various supply chain would be kept in semi-finishedstage and will be

Fig 1. Methods to achieve mass customization. Adapted from Selladurai (2004)

finalized when the order will arrive or rises. In the current market scenario, PP is a necessity to opt for and not a mere concept to be studied (Van Hoek, 2001). Initially PP was studied and understood as, delaying the supply chain activities to as late as possible just to minimize the inventory and the costs associated with it. But now, it is an

integrated management activity in fact there are some supply chain activities that cannot be performed until order from customers are received (Van Hoek, 2001). PP activities are very diversified i.e. it has a very wide range of applications from medical field to engineering to management (Kisperska and Swierczek, 2011). The authors proposed different PP activities according to the amount of delaywhen product gets its final shape and is delivered (Yeung et al., 2007). In terms of production industry, there is manufacturing PP and logistics PP. Manufacturing PP refers to those manufacturing and processing activities that is delayed till the customer's order is received whereas Logistics PP refers to time and place postponement.

Yang and Burn (2003), draws a relationship figuring out Speculation-postponement strategy and standardization-customization concept in a single figure. Engineering to order (ETO) components are purely customized products and can be placed in Pure PP category. Make to order (MTO) components have tailed customization and can be placed in Manufacturing PP. Final manufacturing or assembly to order (ATO) components have customized standardization and can be placed in Assembly PP category. Shipment to order (STO) components holds segmented standardization and thus can be placed in Logistics PP category. Lastly, make to forecast (MTF) products (exhaustible products) which company's make and dump to market are purely standardized products and is placed in pure speculation category.

PP can be beneficial to the companies which are operating worldwide. When demand arrives, companies can customize their products according to demand/ requirement of the customer and the practices being followed in the particular country (Van Hoek, 2001).

TABLE 1: Postponement opportunities (adapted from Van Hoek, 2001)

	Traditional operations	Postponement opportunities in operations
Uncertainties	Limited operations; unpredictability about order mix and volume.	Reduce risk of volume and variety mix bydelaying finalization of products.
Volume	Produce volumes (flow shop) with largeeconomies of scale.	Make batches of one (job shop forcustomization, flow shop elsewhere).
Variety	Create obsolescence risks.	Presume, customize, requiring flexibility.
Lead times	Involve long response times.	Offer accurate response, yet perform activities within order cycle time.
Supply chain approach	Limit variety to gain efficiency advantages.	Reduce complexity in operations, yet possiblyadd flexibility and transport costs.

A number of list of practices are there to achieve mass customization of goods as highlighted by Pine II (1993) and Daugherty (1992) are compiled below. These are total seven in numbers.

- a. Create customizable products and services that can be modified by customers (includes design also.). For example bakery products, self-fitting clothes etc.
- b. Simplify components to promote customizing of finished products and services (including design, manufacturing, distribution and marketing).
- c. The customization should turn around standardized products or services (including logistics and marketing functions).
- d. Reducing the response time in the supply chain i.e. providing quick response (including design, manufacturing, distribution and marketing).
- e. Provide point-of-sale or point-of-delivery customization (involving marketing functions). For

example providing fitting of clothes in store, making different shades of paints in store etc.

- f. Proposing Logistics support to proportional mix (such as sales promotion and public relations).
- g. Proposing tailored logistics service level such as regionally targeted distribution.

3. PROS AND CONS OF POSTPONEMENT

PP is intentionally delaying activities rather than waiting for the demand to arise. Over time PP utilization has surrounded whole supply chain from the product design to manufacturing to dispatch of the same. Forecasting at component level is way better than at final finished product level. It was initially introduced as a strategy to reduce the uncertainty and risk and the costs associated with it. PP concepts have often being used in collaboration with Just in Time concept (Yang and Yang, 2010). The table 2 shows the various impacts of having postponement in the supply chain.

TABLE 2: Operating characteristics relevant to Postponement. (adapted from Van Hoek, 2001)

Factor	Impact of postponement
Technological characteristics	
Limited complexity of final manufacturing operation	Limited loss of economies of scale through postponement and short processing times
Limited complexity of technological content in final manufacturing	Short set-up and changeover times, short processing times
Modularity	Rapid final manufacturing at low processing costs, increased possibility to adjust products to markets
Process characteristics	
Possible to decouple primary and secondary production system	a technical pre-condition and needed for manufacturing within the lead time.
Limited complexity of final manufacturing process	Short set-up and changeover times, short processing times
Sourcing from multiple locations	Direct bulk shipments of modules
Product characteristics	
High commonality of modules	Lowered inventory levels and reduced risk of obsolete inventories
Product variety specific formulation of products, specific peripherals/packaging	Improved customization possible
High value density/unit value of products	Reduced pipeline expenses and inventory carrying costs
Product's cube and/or weight increases through customization/final manufacturing	Reduced transportation and inventory carrying costs
Market characteristics	
Short product life cycles/fashion cycles	Less risk of obsolete inventories
High sales fluctuations	Reduced inventory levels and less risk of obsolete inventories
Short and reliable lead times required	Improved delivery service
Price competition	Lowered cost levels
Varied and (physically) fragmented markets	Better targeting, segmentation, and positioning of products and sales

To avoid the delays caused by PP activities, some of the processes are combined to one or are done parallel or by sequencing activities, thus allowing functional integration. Companies centralize inventories, sometimes to serve a number of countries (as in European Distribution Centres). Sometimes PP reaches to the customer as in do-it-yourself

products (Yang and Burns, 2003). Table 3 shows the key factors in the implementation of PP across supply chain. The various positive effects of PP is highlighted in table 4. Table 5 shows the factors that are threats and have negative impact on a firm.

Incompatible communication/information system with suppliers and customers.	Sreedevi and Saranga (2017); Yang et al. (2005);
Intricate and direct distribution.	Yang et al. (2005);
Implementation would be too costly.	Yang et al. (2005);
Government Regulations.	Yeung et al. (2007); Yang et al. (2005)
Firms that have high environmental uncertainty are exposed to high supply risk, high manufacturing process risk and high delivery risk.	Sreedevi and Saranga (2017); Pagh and Cooper (1998); Yeung et al. (2007)

4. CONCLUSION

The Postponement has emerged as one of the most essential supply chain activity from the past decade (Sreedevi and Saranga, 2017). This practice is being listed in the literature in the early 60's till today. To be in the market competition today, the companies are forced to provide a number of options in products and also had to provide a high level of customization. These all factors bring major uncertainties in the entire supply chain. If the company is not able to cope with these uncertainties, the entire supply chain will crumble due to high market pressure and competition. This paper will clear the perception about PP activities highlighting its various benefits by comparing with traditional manufacturing. Factors affecting implementation, the benefits and deprivation are further listed at the later stage.

Abstract: Increased industrialization in the last decade is creating significant pressure on manufacturers to focus on environmental management. Organizations under no condition ignore the environmental issues and in fact have started searching for sustainable solutions. Remanufacturing supply chain (RSC) helps organization reduce their environmental risks thereby improving their environmental performance and also provides competitive advantage in the market. Selecting the criteria for RSC performance measurement is a strategic decision. Many studies have been carried out to identify the success factors for RSC; however there exists few when it comes to weighing of each criterion according to its importance. The present study first identifies the success factors for RSC through literature study. However, each of these drivers will have varying weightings in the decision making process. Further an Analytical Hierarchy Process (AHP) technique is used to determine the importance of each criterion. Expert opinion in the proposed field has been taken to demonstrate the methodology.

Keywords: Remanufacturing Supply Chain (RSC), Critical Success Factors (CSFs), Analytical Hierarchy Process (AHP)

1. INTRODUCTION

Environment, the natural provider of resources and also the sink to dispose the end-of-life/end-of-use products and waste is being exploited due to unethical human activities in the last few years, thus resulting into an unsustainable environment. There is increasing need that the manufacturing industries address these problems and tend to increase their production with minimum use of raw materials and natural resources, thus addressing the sustainable issues in the manufacturing activities. Manufacturers need to come out of the traditional thinking and incorporate sustainable strategies in their activities to reduce wastage. This is why manufacturing firms, especially original equipment manufacturers (OEMs) and their suppliers, are under increasing pressure from stakeholders, including regulators, customers and employees to produce ethically, reuse/recycle, remanufacture, and/or to safely discard their waste in accordance with the absorptive and regenerative capacity of the planet (Barker and Zabinsky, 2011).

Researchers attempt to address the above issues by developing different sustainable strategies such as modular design, cleaner production (Xia et al., 2015) and reuse and recycling (Wu et al. 2017). Undoubtedly these strategies best support sustainability but in the last few years, remanufacturing is one such strategy that is finding increased attention in the research community (Goepp, Zwolinski, and Caillaud 2014; Radhi and Zhang 2016). Remanufacturing is a multi-process that involves product

recovery after its end-use, inspection, disassembly, cleaning, refurbishing, reconditioning, upgrading, and reassembly to transform the used product to a “like-new” product (Sutherland et al. 2008; Ke et al. 2011; Kafuku et al. 2016). Remanufacturing has gained attention from research community as well as industrial practitioners due its several advantages such as: eco-efficiency and effectiveness of asset recovery (Nasr and Thurston, 2006); improved profit margins (Wei and Zhao 2015; Diaz and Marsillac 2017; Loomba and Nakashima 2012); and saves the resources along with reduction of emissions to the environment (Yang et al., 2015).

However, there is still a serious concern when it comes to implementation of remanufacturing in Indian industries. Successful implementation of remanufacturing in the existing supply chain is relatively difficult from industrial point of view as most of the industries are unknown of the benefits that can be accrued due its implementation and also lack of standardized process to initiate it (Chan and Kai Chan, 2008). In addition, remanufacturing decision makes the entire system more complicated due to complex relationship between the forward and reverse flow of products. To deal with this uncertainty, scholars and practitioners attempt to isolate the important determinants of initiation and implementation of RL among industries (Vijayan et al., 2014). A study is thus needed to identify the essential critical success factors for remanufacturing implementation in the existing supply chain.

Remanufacturing supply chain being multi-faceted and further an attempt to implement it demand to identify key critical success factors. These factors share a complex interrelationship amongst them. Also, the factors for successful implementation of remanufacturing in supply chain may turn out to be either qualitative or a few quantitative, hence a suitable technique is very much needed to handle the complex situation of a multi-dimensional problem. Under such circumstances, it is most appropriate to make use of multi-criteria decision making (MCDM) techniques due to its ability to handle complex parameters at a time.

In this regard the paper aims to study the remanufacturing supply chain with the following objectives:

1. To identify the critical success factors for remanufacturing implementation in supply chain.
2. Analyze the drivers using Analytical Hierarchy Process (AHP).

Analytic Hierarchy Process (AHP) a multi-criteria decision making tool, has been identified to quantitatively analyze the relative significance of the drivers to implement green supply chain. AHP methodology helps top management identify the priority success factors of RSC as it divides complex problem into simple problems using a multi-level hierarchical structure; each level representing set of criteria and sub-criteria.

The rest of the paper is organized as follows: Section 2 covers the literature review on RSC that plays a major role in identification of success factors of RSC implementation. Four important dimensions have been identified in this study. Solution methodology is explained in Section 3. Section 4 consists of data analysis and presents the results. Findings of the results and concluding remarks are discussed in section 5.

2. LITERATURE REVIEW

Literature related to remanufacturing supply chain is discussed in this section. This section is divided into two subsections. The first provides the relevant literature on remanufacturing implementation while the second subsection identifies the drivers of RSC through the study of existing literature.

2.1 RSC

Few studies carried out in Indian context with a focus on remanufacturing are discussed in this section. Mondal and Mukherjee (2006) based on empirical study identifies six critical factors that Indian manufacturers consider before they make their decision to engage into remanufacturing activities or not. Choudhary and Singh (2011) explore the potentiality of remanufacturing growth in India and the challenges that may be faced by the industry, environment and society during its implementation. Rathore et al., (2011) evaluates the present remanufacturing status through a case analysis of India mobile phone to find ways as to how in the present socio-economic environment it can be successfully implemented. Govindan et al., (2016) study is focused on Indian auto parts remanufacturing industries to evaluate the critical barriers. They propose a hybrid approach (ISM-Fuzzy ANP) for analysis.

2.2 Remanufacturing implementation: critical success factors

Effective and efficient implementation of remanufacturing supply chain practices depends on the factors that should be evaluating its performance. The study identifies eight major success factors identified through literature review and subsequent discussion with SC experts, academicians, and industrial practitioners (Senior level, Middle level managers). The identified eight success factors are as described in Table I.

TABLE I: Common critical success factors for implementation of Remanufacturing in a SC

Criteria	Criteria code	Description	Source
Management commitment and involvement	RSC1	Intensify remanufacturing implementation and better coordination and involvement	Subramonium et al., (2013)
Standardized policies from government	RSC2	Provide an organized approach to small enterprise and new organizations through a standardized framework	Sharma et al. (2016)
Effective information flow	RSC3	Proper coordination at each stage of the remanufacturing supply chain	Vasanthakumar et al., (2016)
Technological up-gradation	RSC4	Improve product quality and productivity	Mondal and Mukherjee (2006)
Expertise training	RSC5	Efficient handling of remanufacturing complex production environment	Rathore et al., (2011)
Healthy work environment	RSC6	Increase worker efficiency	Rathore et al., (2011)

Criteria	Criteria code	Description	Source
Research and development	RSC7	Improves product performance and reduce hazard material	Abdulrahman et al. (2014)
Material durability	RSC8	Enhance service life of the components	Abdulrahman et al. (2014)

3. SOLUTION METHODOLOGY: ANALYTICAL HIERARCHY PROCESS

The concept of AHP was developed by an American mathematician, Thomas L. Saaty from the University of Pittsburgh (Saaty, 2008). For various decisions making process Analytical Hierarchy Process (AHP) is one of the

most frequently applied multi-attribute decision making methods.

Steps of AHP Methodology: (1) Identifying the drivers (criteria) and structuring the criteria hierarchy.

(2) Compare the criteria pair wise. (3) Calculating the consistency ratio (4) Calculate the overall priorities of criteria and sub-criteria and identify the important drivers.

Fig. 1 AHP Hierarchy to identify important success factors for remanufacturing implementation

4. DATA ANALYSIS AND RESULTS

Expert opinion is taken for pair wise comparison of matrix at each level of the hierarchy. The maximum Eigen values, C.I. and the priorities of each criterion as obtained by pair wise comparison. One sample of criteria comparison at each Level I and Level II is shown in Table II.

TABLE II: Pair wise comparison matrix for each level of hierarchy

	RSC1	RSC2	RSC3	RSC4	RSC5	RSC6	RSC7	RSC8	Weights
RSC1	1	3	5	3	3	5	3	7	0.2953
RSC2	0.333	1	5	3	4	5	3	6	0.2279
RSC3	0.2	0.2	1	0.25	4	5	0.2	6	0.0808
RSC4	0.333	0.333	4	1	3	4	0.333	5	0.1152
RSC5	0.333	0.25	0.25	0.333	1	3	0.25	4	0.0531
RSC6	0.2	0.2	0.2	0.25	0.333	1	0.2	3	0.0321
RSC7	0.333	0.333	5	3	4	5	1	7	0.1754

CR ≤ 0.1

TABLE III: Normalized weights for success factors for RSC implementation

Drivers (Level I)	Weightings using AHP	Rank
RSC1	0.2953	1
RSC2	0.2279	2
RSC3	0.0808	5
RSC4	0.1152	4
RSC5	0.0531	6
RSC6	0.0321	7
RSC7	0.1754	3
RSC8	0.0202	8

5. DISCUSSION AND CONCLUSION

The present work identifies the success factors of RSC implementation through literature study and demonstrates the use of AHP to evaluate the importance of each driver. Eight main dimensions (Table I) were identified that plays vital role in adoption of remanufacturing practices in a supply chain.

AHP methodology is used to identify the percentage contribution of each criterion. The normalized weight matrix of each criterion (Table III) indicates that the priority weight for management commitment and involvement (0.2952) followed by standardized policies from government (0.2279) are some of the most important practices that needs to be implemented for successful implementation of remanufacturing in a supply chain. The study helps the decision makers to identify the important factor that should be focused to achieve the organizational goal and improve their sustainable performance.

Abstract: Supply chain partnership leads to increased information flows, reduced uncertainty, and a more profitable supply chain. Effective supply chain practice and information sharing enhances the current supply chain management environment. Effective information sharing significantly enhances effective supply chain practice. Information exchange is a very important issue for coordinating actions of units. Accurate and reliable information is needed to support decision-making processes. Due to the large number of participants typically involved in supply chain operations, organizations often find that it is difficult to effectively share information within a supply chain; hence, this research examined ways to improve information sharing within supply chain operations for one marine transportation services organization. The AHP is a flexible multi-criteria decision-making method which can be used to effectively synthesize the judgments given by a team of experts in order to make better decisions in complex settings, where both tangible and intangible criteria must be considered. It is a powerful decision-making methodology for determining the priorities among number of different criteria.

Keywords: Information Sharing, Supply Chain, Supply Chain Management, Fuzzy AHP, Barriers, Major-criteria, Sub-criteria, Decision maker.

1. INTRODUCTION

Because of globalization, serious rivalry and innovative blast as of late, it is critical to viably arrange a wide assortment of associations by sharing essential data (Pujara et al., 2012; Yee, 2005). The information sharing is an all-around acknowledged method where associations by and large compose the supply, generation, and circulation of items and administrations (Chandra et al., 2007). The side effect of information sharing on supply chains (SC) has passed out to be more critical with late approach in Information Technology (IT). Besides, a few examinations have been led to concentrate on the effect of information sharing on item aspect (Lotfi et al., 2013). To upgrade the after effects of information sharing, management ought to answer four fundamental queries: First we ask that what to share, then whom to share with, then how to share, lastly when to share. The description of answers will dodge repetition, lessen sharing expenses and enhance reactions (Robinson and Sahin, 2005). IS allows to the sharing of private and optional information, which is past the information required to complete the everyday exchange

among purchasers and merchants (Yigitbasioglu and Organ, 2010).

2. LITERATURE REVIEW

The coordination of an organization supply chain with numerous providers, with which information sharing is crucial or important, since it can frequently improve the execution of the supply chain, yet may build up and strengthen the opposition among individuals in the chain (Ho et al. 2017). Information sharing in a SC comprising of one provider and one retailer, in which both of them two estimate the request under make-to-stock and make-to-request situations (Mishra et al. 2009). In current business; rivalry is no longer between organizations, yet among supply chains. Supply chain is unpredictable in nature, including different work streams crosswise over exchanging accomplices (Wu et al. 2014). The impact of information sharing among business accomplice's on-time conveyance rate and aggregate cost is researched by means of recreation of a nonspecific, speculative supply chain model (Hall et al. 2012)

TABLE 1 Initial hierarchy model of barriers of IS adoption in SC and its criteria

Main criteria	C. code	Sub criteria	References
Strategic barriers	SB 1	Lack of customer oriented vision	Costantino et al. (2015); Wo et al. (2014)
	SB 2	Lack of Strategic planning	Bain et al. (2016); Bonzon et al. (2016)

Main criteria	C. code	Sub criteria	References
	SB 3	Lack of IS between SC members	Pujara et al. (2013)
	SB 4	Lack of SC benefits	Manzouri et al. (2010)
	SB 5	Lack of SC integration	Zhor et al. (2007)
	SB 6	Inadequate clear understanding of IS	Prakash et al. (2015)
Organizational barriers	OB 1	Deficiency of improved mutual sharing trust	Ye et al. (2013)
	OB 2	Improper organization structure	Manzouri et al. (2011); Parcin (2008)
	OB 3	Lack of top management support	Senthil et al. (2012); Costantino et al. (2015)
	OB 4	Improper flow of information	Prakash et al. (2015)
	OB 5	Lack of enhanced adaptability	Jeong et al. (2012)
	OB 6	Long term relationship among supply chain members	
	OB 7	Diminishing organization power	Singh et al. (2008)
Financial barriers	FB 1	Shortage of fund for training and education	Zhang and Chen (2013)
	FB 2	Required resources for operational use	Sohal et al. (2012)
	FB 3	Inadequate fund related offices for equipment	Ganesh et al. (2014)
	FB 4	Lack of cost sharing benefits	Parcin (2008)
Technological barriers	TB 1	Inefficient technological advancement	Cheung et al. (2012); Gunasekaran and Ngai (2004)
	TB 2	Risk of data loss	Kumar et al. (2012); Kaynak et al. (2012)
	TB 3	Trouble in classifying strategy information	Kembra et al. (2015); Lotfi et al. (2013)
	TB 4	Absence of service exchange	Lee et al. (2006)
Human-based barriers	HBB 1	Lack of employee motivation and reward	Bouzon et al. (2016)
	HBB 2	Confidentiality of the SC information shared	
	HBB 3	Lack of supportive culture	Ganesh et al. (2014); Pujara et al. (2013)
	HBB 4	Lack of time to share information	Lau et al. (2009)
	HBB 5	Fear of shame for sharing wrong data	Pillai et al. (2010); Willem et al. (2007)

3. FUZZY AHP APPROACH

Computational technique of fuzzy analytic hierarchy process. The analytic hierarchy process strategy is otherwise called an eigenvector strategy. It shows that the eigenvector relating to the biggest eigen-value of the pair wise examinations matrix gives the relative needs of the components and preserves ordinal desire among the options. This implies if an option is wanted to another, its

eigenvector part is bigger than that of the other. A vector of weights gotten from the pair wise examinations matrix mirrors the relative execution of the different components. In the Fuzzy AHP, TFNs are used to enhance the scaling plan in the judgment frameworks and interim math is utilized to unravel the fuzzy eigenvector (Cheng et al, 1994). Below table is used for pairwise comparison for criteria

TABLE 2: Linguistic variable for solutions ratings.

Intensity of importance	Fuzzy number	Linguistic variables	Membership function
1	$\tilde{1}$	Equally important/preferred	(1, 1, 3)

Intensity of importance	Fuzzy number	Linguistic variables	Membership function
3	$\tilde{3}$	Weakly important/preferred	(1, 3, 5)
5	$\tilde{5}$	Strongly more important/preferred	(3, 5, 7)
7	$\tilde{7}$	Very strongly important/preferred	(5, 7, 9)
9	$\tilde{9}$	Extremely more important/preferred	(7, 9, 11)

The next step is to build fuzzy comparison matrix by utilizing the above TFN table with the help of industrial experts. Since due to space limitation only one FCM are shown here similarly same approach is applicable for all major and sub criteria.

TABLE 3: FCM for major criteria

Attributes	Strategic	Organizational	Financial	Technological	Human-based
Strategic	1	$\tilde{1}^{-1}$	$\tilde{5}$	$\tilde{1}$	$\tilde{7}$
Organizational	$\tilde{1}$	1	$\tilde{7}$	$\tilde{3}$	$\tilde{9}$
Financial	$\tilde{5}^{-1}$	$\tilde{7}^{-1}$	1	$\tilde{3}^{-1}$	$\tilde{1}$
Technological	$\tilde{1}^{-1}$	$\tilde{3}^{-1}$	$\tilde{3}$	1	$\tilde{5}$
Human-based	$\tilde{7}^{-1}$	$\tilde{9}^{-1}$	$\tilde{1}^{-1}$	$\tilde{5}^{-1}$	1

The overall consistency (CR) ratio of all criteria matrix and all over inconsistency for the hierarchy can be analysis and control the overall result of this approach. The CR value can be found out as:

Determine the highest Eigen value by utilizing the below equation.

$$\tilde{A}\tilde{x} = \tilde{\lambda}\tilde{x}$$

$$CR = \frac{CI}{RI}$$

$$CI = \frac{\lambda_{\max} - n}{n - 1}$$

Where CI represents consistency index and RI is random index. The value of RI can be taken as per the table shown below.

TABLE 4: Random index value

n	1	2	3	4	5	6	7	8
RI	0	0	0.52	0.89	1.11	1.25	1.35	1.40

If the CR for a comparison matrix is less than 0.10 then the comparisons are acceptable, otherwise not. If the value does not found to be less than 0.10 then decision maker has to revise the authentic values in the pair wise comparison

matrix. And finally rank the barriers by giving weight to them in decreasing order.

4. APPLICATION ON CASE ORGANIZATIONS

In today's scenario many Indian manufacturing organizations understand that IS plays a crucial role for success of business and IS adoption in SC is going to be a core importance. Some manufacturing organization have taken IS integration with SC. But the rate of success was quit low due to presence of barriers in IS adoption in SC. In order to increase the rate of success the main thing is to shortlist these all barriers and rank them as per there priorities. Since implementing all criteria at the same time which is a tough task. Hence it is crucial to rank these barriers of IS adoption in SC, hence, manufacturing organization can put on barriers and implement in a proper stepwise sequence. The case organization X, interesting in implementing information sharing because it suffers pressure from current competitive challenges from others organization which is dealing with the same operation. Organization X is an Indian manufacturing company with turnover of more than 52crores and over 500 employees and 25 suppliers and venders. Organization engaged in design, manufacturing, and marketing of electrical equipment related to power generation, transmission, and distribution. This company shows interest to find out and rank the barriers of IS adoption in SC. Below table shows the weight of major criteria similarly weight of all sub criteria can be calculated.

TABLE 5: Final weight for major criteria

Major Criteria		Major Criteria Weight
Strategic barriers	=	0.286108049
Organizational barriers	=	0.427783903
Financial barriers	=	0.060639471
Technological barriers	=	0.183572216
Human-based barriers	=	0.041896362

The judgment for ISBs display has been dissected with the assistance of CR and discovered logical as it is satisfying the situation yet in the event that some way or another it neglects to satisfy the situation for the consistency then

expert need to replay the pairwise observation prepare until the situation for consistency has been come to. After the consistency test for matrix 'A', standardization of the GCCMmaj is finished. The significant criteria weights are condensed: Strategic barriers (0.2061), Organizational barriers (0.4277), Financial barriers (0.0606), Technological barriers (0.1835), Human-based barriers (0.0418).

By taking after the comparative figuring, fuzzy comparison matrices for sub criteria were changed into crisp correlation matrix and their significant standard weight, CR, proportion weight for Strategic barriers, Organisational barriers, Financial barriers, Technological barriers, Human-based barriers. There were ascertained utilizing PC program.

TABLE 6: Final priority of Information Sharing Barriers

Main Criteria	Major Criteria Weight	Sub Criteria Code	CR	Ratio Weight	Final Weight	Rank
Strategic barriers	0.2861	SB 1	0.0803	0.14989	0.04288	9
		SB 2		0.4415	0.12633	2
		SB 3		0.0790	0.02260	13
		SB 4		0.04599	0.01315	17
		SB 5		0.2570	0.07353	5
		SB 6		0.02651	0.00758	22
Organizational barriers	0.4277	OB 1	0.0886	0.0650048	0.02780	12
		OB 2		0.2394916	0.10245	3

Last weight of the sub criteria can be computed by multiplying the major weight of each ISB and proportion weight of each ISB.

5. RESULTS, DISCUSSIONS, CONCLUSIONS AND FUTURE SCOPE

It is difficult to state beyond any doubt which barriers of IS selection in SC is very crucial, yet the positioning procedure by utilizing fuzzy AHP methodology made it extra extensive and organized. This method utilized as a part of an Indian manufacturing was planned to enhance the achievement amount of IS selection in SC. This will be accomplished by actualizing the result of IS selection in SC by stepwise way to blown-away its barriers. Ultimately total 26 are distinguished by writing audit and decision maker request. The weight of the hurdles of IS selection in SC figured by fuzzy AHP and based upon their value ranking had been done in decreasing order.

The ISBs have been summed up and might be lacking or certain for some particular industries. This procedure may observe to be useful for directors to touch base at basic ISBs for their businesses. The overall results shows that the combination of fuzzy decision making with AHP could become a useful tool in future research. For the future research, fuzzy system could be stretched out with the other MCDM strategies, for example, Analytical Network Process (ANP), TOPSIS.

Abstract: With growing complexity in supply chains, it became necessary to incorporate these complexities into the models. In this paper, the authors propose a model for coordination of production and distribution planning for a supply chain with third party logistics. In 3PL, the transportation facilities (vehicles) are owned by private parties (i.e. they are not owned by plant owners). In this type of distribution, the plant managers and distribution service providers share partial information. They will not share information about their capacities and costs, because of lack of trust. But share information such as the desired production quantity by the distributors and possible production quantity by the plant managers. Under such situations, the model proposed in this paper is appropriate. The authors tested the model for problems generated with uniform random numbers between minimum and maximum values for the costs and capacities. The results indicate that the proposed model can be applied to real life problems where third party logistics are involved.

Keywords: Multi Product SCM, Agents in SCM, Third Party Logistics, 3PL

1. INTRODUCTION

The production – distribution planning models of supply chains can be considered broadly as two types. In the first types of models there is complete information sharing and the channel partners (production managers and distributors (transporters) share complete information between them. The distributors and manufacturers share information about their capacities and costs. In this type of supply chain models, there is single objective function which minimizes the sum of distribution related and production related costs subject to constraints on plant and inventory capacities and inventory balance constraints. This type of models is appropriate when the transportation facilities (vehicles) are owned by the plant owners.

In the second type of models, there is partial information sharing between the distributors and manufacturer's. The distributors will not share information about distribution costs, and distribution capacities. But they will share information about desired production quantity required from the manufacturers to minimize their distribution costs. Similarly the manufacturers will not share information about production capacity and production costs but will share information about possible production quantity, to the distributors, considering their plant capacities. In this type of supply chain models, there are two objective functions, one each for distribution and production, to minimize their respective costs. In addition, there is a coordinating mechanism which modifies the capacities of production and distribution according to an algorithm. Each of the

production and distribution problems is modeled as an agent. Each agent has an objective and there is only partial information sharing between the two agents. Each agent tries to locally optimize its own objective function. Finally there is a coordination mechanism between the two agents to arrive at the final optimal plans for production and distribution.

The Paper is organized as follows. Brief literature review is carried out in section.2. The proposed model is presented in section.3. The methodology is presented in section.4. The data set used in this paper is presented in section. 5. Implementation details are mentioned in section. 6. Results are discussed in section. 7. Finally the paper concludes in section 8..

2. LITERATURE REVIEW

Hosang Jung (2005) et al has proposed a decentralized production-distribution planning system using collaborative agents in supply chain network. In their work, they considered two agents, one each for production and distribution functions.

Tatsushi Nishi (2006) et al has proposed an autonomous decentralized supply chain planning and scheduling system in which three autonomous agents are used to represent the material requirement planning (MRP), Scheduling and Distribution planning (DP) functions of a supply chain .

Martin Albrecht (2015) et al has proposed a system of coordinating decentralized linear programs by exchange of

primal information. The authors have mentioned, that exchanging primal information, rather than the dual information has the advantage that the plant managers know about what information they are exchanging.

KavehKhallili (2016) et al has considered uncertainty in demand and formulated centralized and decentralized production distribution planning problem in supply chain with uncertainty. They used fuzzy mathematics to model the uncertainty in demand at the retailer..

3. PROPOSED MODEL

The proposed model consists of three echelons (levels), namely plants, Distribution centers (warehouses), and customer zones. The problem is modeled by two software agents (two linear programs), one each for distribution and production.

3.1.DISTRIBUTION AGENT(DA)

The Costs of DA include distribution related costs like tardiness costs, earliness costs, distribution costs from plant to warehouses, and distribution costs from warehouses to customer zones. Tardiness costs are incurred when a product is delivered after its' due date. The tardiness costs reflect the reputation and goodwill lost by the firm by delivering a product after its due date. Earliness costs are incurred when a product is delivered before its' due date. The objective of distribution agent is to minimize the sum of tardiness cost, earliness cost, distribution costs from plants to distribution centers and from distribution centers to customer zones for all the products in all periods. The distribution agent will minimize his objective function subject to constraints such as meeting the demand at customer zones, Inventory balance constraints and limit on maximum earliness quantities. That is, the Distribution agent (DA) is a linear program

3.2.PRODUCTION AGENT(PA)

The production related costs include the manufacturing costs, inventory holding costs and stock out costs. The objective of Production agent (PA) is to minimize the sum of production related costs mentioned above. The PA will minimize the production related costs subject to constraints on inventory balance constraints, production and inventory capacity constraints. The shortage costs are fixed at a high value so as to prefer production to shortage situation

4. METHODOLOGY

Initially, the distribution agent will minimize the distribution related costs subject to its' own constraints. During this process the DA will not consider the plant capacity constraints. The DA will communicate to PA, the **desired production quantity**. The **desired production quantity** for a given product at a given plant in a given time period is calculated as the sum of distribution quantities of

that product in that period from all distribution canter to that plant. This **desired production quantity** is communicated by the DA to PA. Now the PA will use this **desired production quantity** and production and inventory capacity constraints to minimize production related costs. That is the PA will determine the **possible production quantity**. Using this **possible production quantity**, the **plant capacity** is **modified** according to an algorithm. This **ModifiedPlant Capacity** is communicated to the DA and the DA will minimize the distribution related costs with the addition of the new constraint that the **distribution quantity** of all products between plant and distribution centre in a given period will not exceed the **Modified Plant Capacity**. The variables that are exchanged between the DA and PA are shown by bold letters. This iterative exchange of information between the DA and PA is continued until there is no planning gap. That is the desired production quantity is not greater than the possible production quantity.

5. DATA SET

In this Paper, for implementation purpose, a supply chain with two plants, two distribution centers and four customer zones is assumed. Each plant is assumed to produce 8 products. The time horizon for the problem is 12 periods.

Four test problems with different costs (seven costs – Four costs for DA and three costs for PA) and capacities (three capacities – plant capacity, inventory capacity, and limit on earliness quantity) have been generated with uniform random integers between minimum and maximum values. The ranges of these values have been shown in Table.1.

6. IMPLEMENTATION

The proposed model has been modelled in General Algebraic Modelling System (GAMS 24.7.4) software. CPLEX MIP solver has been used to solve all the test problems

7. RESULTS

The summarized results for all the four test problems have been shown in pie charts for test problems 1, 2, 3, 4 in iteration no.1 and 15. The summarized results for all the four test problems are also shown in Table.2 for test problems 1, 2, 3, 4 in iteration no.1 and 15. In Table.2 the share of each channel in total cost is shown for iteration.1 and iteration.15.. As can be seen from the table, the share of DA in total cost is increasing and that of PA is decreasing. This behaviour is due to the negotiation between the two agents, DA and PA.

The share of each channel (DA, PA) in the Total costs is shown in pie chart. In Fig.1 and Fig.2.The convergence graph of the algorithm is shown in Fig.3.. In Fig.3, iteration No. is taken along the x axis and DA Cost, PA Cost and Total Cost values are shown on the y axis.

8. CONCLUSION

In future, the proposed model is going to be implemented in MATLAB by solving the model with different Meta heuristics such as GA, PSO, ABC, etc. and a comparison will be made.

Modeling Carbon Footprint across Food Supply Chain

Ajit Kumar Pandey¹, Ravi Kant², Md. Mamun Habib³

^{1, 2} Department of Mechanical Engineering, S.V. National Institute of Technology, Surat, Gujarat, India.

³ BRAC Business School (BBS), BRAC University, Dhaka, Bangladesh

Abstract: In the supply chain management, the environment effect is one imperative concern carbon footprint is a famous metric to evaluate an item's greenhouse gas (GHG) emissions, and help supply chain management. The focus of this paper is to assess low carbon supply chain in the food industries. So that paper optimises the carbon footprint across supply chains and also introduce indirect carbon emission concept in a network optimization model for sustainable chain management. The proposed model optimize total cost, total direct carbon emission, total indirect emission in the form of embodied carbon footprint of raw material and total trade credit amount over the purchased item in supply chain and to find a compromised solution of these objectives using multi objective goal programming.

Keywords: Low-carbon supply chain, carbon footprint, carbon emission, goal programming.

1. INTRODUCTION

Sustainable development is the main accessible and viable approach to enhance the competitiveness of a supply chain (Shaw et al., 2013). GHG emission of Sustainable production and utilization requires powerful "green" supply chain management to produce both economic and ecological advantages by minimizing waste, limiting contamination, reduction energy waste, conserving natural resources, and decreasing carbon emissions (He et al., 2016). The meaning of carbon footprint and suggested that embodied carbon footprint should represent measuring the aggregate carbon footprint of product (Shaw et al., 2013). The carbon footprint is a measure of the elite total sum of carbon dioxide outflows that is specifically and by implication brought about by an action or is collected all over the life phases of a product (Xia et al. 2013). The supply chain carbon footprint is the aggregate carbon footprint of all organizations in it (He et al. 2016). For deciding the carbon footprint of any item go along its whole life stages, the greenhouse gases emission occurs at the every stage of the life cycle like input and raw materials through manufacturing, distribution, consumer utilization (Roibas et al., 2016). Transportation is the biggest wellspring of emanations in the logistic system. Consequently, appropriate optimization of the supply chain may decrease the emission of a supply chain (Shaw et al., 2016).

2. LITERATURE REVIEW

He et al. (2016) centers to assess the effect of buyer free riding on carbon emissions in an item's life cycle over a dual channel closed loop SC and to evaluate the impact of governmental e-commerce tax on carbon emissions. . Bevilacqua et al. (2011) argue that many organizations concentrated their consideration on environmental effect of their items and use the LCA procedure to decide the carbon

footprint of various players required in a supply chain of the textile sector. Shaw et al. (2016) suggested that to constrained based green supply chain network design model show tending to carbon emissions and carbon exchanging issues. The model decides the ideal full of materials and also emissions over the SC network. Shaw et al. (2013) present indirect carbon emission and trade-credit idea in a network optimization model for sustainable supply chain. Xia et al. (2013) concentrate about on carbon footprint, production optimization theory individual enterprise and supply chain operation administration with carbon emissions constraints. A life cycle assessment model build up to evaluate the carbon footprint of the industrial production and distribution of 1 hL of lager beer in various packaging (Cimini et al., 2016). Roibas et al., (2016) aim to computed carbon footprint of Ecuadorian bananas, comprehensive of the utilization point in Spain, was 1.28 ton CO₂e per ton of banana because Bananas are most imperative food crops in the world. Van der Vorst et al. (2009) argue that food supply chain is confronted with expanded customer demands on food quality and sustainability. The extensive literature reviews were carried out for low carbon supply chain performance.

3. GOAL PROGRAMMING

Goal programming (GP) is developed and advanced by Charnes and Cooper (1997). GP is capable technique in the field of multiple decision making problem. GP is generally used to optimize the multi objective problem (Shaw et al., 2013). The overall objective function of the model is tried to minimise any deviations from specified goals (Nixon et al., 2014). In this paper is dealing with various clashing objective. Therefore, GP is good enough technique for finding a compromising solution (Shaw et al., 2012). In this paper, used goal programming is weighted goal programming to get the best compromise or satisfactory

solution of the model. A weighted goal programming can be written as

$$\text{Min } \sum_{i=1}^n (\alpha_i s_i^+ + \beta_i s_i^-)$$

Subjected to,

$$f_i(X) - s_i^+ + s_i^- = g_i, i = 1, 2, \dots, n$$

$$s_i^+, s_i^- \geq 0 \quad i = 1, 2, \dots, n$$

$X \in F$ (F is a feasible set)

Here α_i and β_i are the individual positive weights add to these deviational variables in the achievement function; $s_i^+ = \max(0, f_i(X) - g_i)$ and $s_i^- = \max(0, g_i - f_i(X))$ which are over and under achievements of the i th goal, respectively.

3.1 Model Development

Model has considered four objective functions. These objectives functions are: (i) To minimise the cost, (ii) To minimise the carbon emission, (iii) To minimise the embodied carbon footprint and (iv) To maximise the trade-credit amount over the purchasing cost. The cost and trade-credit are calculated in rupees (₹). The carbon emission and embodied carbon footprint are expressed in kilograms (kg). All the required sets and variables are shown in the following formulation.

3.1.1 Sets

I	Set of suppliers, indexed by i
J	Set of manufacturers, indexed by j
K	Set of customers, indexed by k
M	Set of different type of trucks, indexed by m
T	Set of time periods, indexed by t

3.1.2. Parameters

PC_{ijt}	Purchasing cost/material purchased (from supplier i by manufacturer j at a time period t)
ECF_{ijt}	Embodied carbon footprint of the material purchased (from supplier i by manufacturer j at time period t)
CP_{ijt}	Credit percentage over the amount of material purchased (from supplier i by manufacturer j at time period t)
$UTCSM_{ijmt}$	Transportation cost/material (from supplier i to manufacturer j using truck m at time period t)
$UTCMC_{jkmt}$	Transportation cost/material (from manufacturer j to customer k using truck

	m at time period t)
$UHCSM_{ijt}$	Holding cost/material (from supplier i to manufacturer j at time period t)
$UHCMC_{jkt}$	Holding cost/material (from manufacturer j to customer k at time period t)
$TCESM_{ijmt}$	Carbon emission in transportation/material (from supplier i to manufacturer j using truck m at time period t)
$TCEMC_{jkmt}$	Carbon emission in transportation/material (from manufacturer j to customer k using truck m at time period t)
UMC_{jt}	manufacturing cost/product (for manufacturer j at time period t)
CEM_j	Carbon emission for manufacturing/product (at manufacturer j)
S_{it}	Capacity of the supplier i at time period t
Q_{jt}	Capacity of the manufacturer j at time period t
CT_{mt}	Transportation capacity of truck m at time period t
D_{kt}	Demand of customer k at time period p

3.1.3 Decision Variables

X_{ijmt}	Transferred quantity from supplier i to manufacturer j at time period t by using truck m
Y_{jkmt}	Transferred quantity from manufacturer j to customer k at time period t by using truck m
Z_{jt}	Manufactured quantity by manufacturer j at time period t

3.1.4 Deviation variables

$\square_a^-, s_a^+$	Under achievement and overachievement from total cost of supply chain goal/target, respectively
s_b^-, s_b^+	Under achievement and overachievement from carbon emission goal/target, respectively
s_c^-, s_c^+	Under achievement and overachievement from embodied carbon footprint goal/target, respectively
s_d^-, s_d^+	Under achievement and overachievement from trade credit goal/target, respectively

3.1.5 Model

The objective of GP model is to minimise the deviations from the goals/targets. Objective function (1) minimizes the weighted deviations around the goals/targets. In this

equation, s_a^+, s_b^+, s_c^+ and s_d^- are the deviational variables of cost, carbon emission, embodied carbon footprint and trade credit goals, respectively, and $\alpha_a, \alpha_b, \alpha_c$ and β_d are the corresponding weights of the above deviations of goals.

$$\text{Minimize} = \alpha_a s_a^+ + \alpha_b s_b^+ + \alpha_c s_c^+ + \beta_d s_d^- \quad (1)$$

$$\text{Total cost goal (A) = Total purchasing cost + Total transportation cost + Total handling cost + Total Production cost} + s_a^- + s_a^+ \quad (2)$$

where

$$\text{Total purchasing cost} = \sum_{i=I} \sum_{j=J} \sum_{t=T} P C_{ijt} \sum_{m=M} X_{ijmt} \quad (3)$$

$$\begin{aligned} \text{Total transportation cost} &= \sum_{i=I} \sum_{j=J} \sum_{m=M} \sum_{t=T} X_{ijmt} U T C S M_{ijmt} \\ &+ \sum_{i=I} \sum_{j=J} \sum_{m=M} \sum_{t=T} Y_{jkm t} U T C M C_{jkm t} \end{aligned} \quad (4)$$

Total handling cost =

$$\begin{aligned} &\sum_{i=I} \sum_{j=J} \sum_{t=T} U H C S M_{ijt} \sum_{m=M} X_{ijmt} \\ &+ \sum_{j=J} \sum_{k=K} \sum_{t=T} U H C M C_{jkt} \sum_{m=M} Y_{jkm t} \end{aligned} \quad (5)$$

$$\text{Total production cost} = \sum_{j=J} \sum_{t=T} Z_{jt} U M C_{jt} \quad (6)$$

Total carbon emission goal (B) = Emission for transporting the material from suppliers to

$$\text{Manufacturers + Emission for transporting the material from Manufacturers to customers + Manufacturing carbon emission} + s_b^- - s_b^+ \quad (7)$$

Where

Emission for transporting the material from suppliers to manufacturers

$$= \sum_{i=I} \sum_{j=J} \sum_{m=M} \sum_{t=T} X_{ijmt} T C E S M_{ijmt} \quad (8)$$

Emission for transporting the material from manufacturers to customers

$$= \sum_{j=J} \sum_{k=K} \sum_{m=M} \sum_{t=T} Y_{jkm t} T C E M C_{jkm t} \quad (9)$$

Manufacturing carbon emission

$$= \sum_{j=J} C E M_j \sum_{t=T} Z_{jt} \quad (10)$$

Total embodied carbon footprint goal (C)

$$= \sum_{i=I} \sum_{j=J} \sum_{t=T} E C F_{ijt} \sum_{m=M} X_{ijmt} + s_c^- - s_c^+ \quad (11)$$

Trade credit goal (D)

$$= \sum_{i=I} \sum_{j=J} \sum_{t=T} P C_{ijt} C P_{ijt} \sum_{m=M} X_{ijmt} + s_d^- - s_d^+ \quad (12)$$

All the constraints of the model are illustrated in (13)–(22).

$$\sum_{j=J} \sum_{m=M} X_{ijmt} \leq S_{it} \quad \forall i \in I, t \in T \quad (13)$$

$$\sum_{k=K} \sum_{m=M} Y_{jkm t} \leq Q_{jt} \quad \forall j \in J, t \in T \quad (14)$$

$$\sum_{i=I} \sum_{j=J} X_{ijmt} \leq C T_{mt} \quad \forall m \in M, t \in T \quad (15)$$

$$\sum_{j=J} \sum_{k=K} Y_{jkm t} \leq C T_{mt} \quad \forall m \in M, t \in T \quad (16)$$

$$\begin{aligned} \sum_{i=I} \sum_{m=M} X_{ijmt} - \sum_{k=K} \sum_{m=M} Y_{jkm t} &= 0 \\ \forall j \in J, t \in T \end{aligned} \quad (17)$$

$$\sum_{i=I} \sum_{m=M} X_{ijmt} - Z_{jt} = 0 \quad \forall j \in J, t \in T \quad (18)$$

$$Z_{jt} \leq Q_{jt} \quad \forall j \in J, t \in T \quad (19)$$

$$\sum_{i=I} \sum_{m=M} Y_{jkm t} \geq D_{kt} \quad \forall k \in K, t \in T \quad (20)$$

$$X_{ijmt}, Y_{jkm t}, Z_{jt} \geq 0 \text{ and integer}$$

$$\forall i \in I, j \in J, k \in K, m \in M, t \in T \quad (21)$$

$$s_a^+, s_b^+, s_c^+, s_d^+, s_a^-, s_b^-, s_c^-, s_d^- \geq 0 \quad (22)$$

4. APPLICATION ON CASE ORGANIZATIONS

The proposed model is explained on a case study of food supply chain. X is a food manufacturing company. The

study considers that X Company has three manufacturing plants in India. All the three manufacturing plants sources raw ingredients from three reliable suppliers. For optimising the SC realistic value have taken. For solving

the model the data sets are shown in Table 1-14. Model has taken, I=3, J=3, K=3, M=3 and T=3 for explaining the case study.

TABLE 1: Costs (₹) of the raw material purchased from different suppliers at different time period.

	3	36500		36500		36500	

Model has the following goals/targets. The goals are cost (A) = ₹633161.4, carbon emission (B) = 96, 150 kg, embodied carbon footprint (C) = 1, 395.4 kg and trade credit (D) = ₹81778. The main focus of model is to minimise the carbon emission and embodied carbon footprint in SC. The first priority of model is to minimise carbon emission and second priority is to minimise the embodied carbon footprint. To achieve these, the following weights have chosen ($\alpha_a = 0.1$, $\alpha_b = 0.4$, $\alpha_c = 0.3$ and $\beta_d = 0.2$) for the deviations of the following goals A, B, C and D, respectively. The model considers that the carbon emission per food product produced in manufacturing plant 1, 2 and 3 is 1.4, 1.1 and 1.3 kg, respectively.

Microsoft Excel 2010 software has used for solving the model. Study found a compromised solution of the model after solving this model in Microsoft Excel 2010 that is represented by Case 1, as show in Table 15. After

running/solving the model, a deviation of ₹31329.9 from total cost goal is found. The positive deviation is 4.94% from the total cost goal. Table 15 shows all the deviational value from the goal. The deviations are 12.40%, 14.02% and 36.46% from the carbon emission (B), embodied carbon footprint (C) and trade credit goal (D), respectively.

If more weights is given on carbon emission and embodied carbon footprint, than found that maximum number of material/product are transported by Truck 3, because Truck 3 emits lesser CO₂ in comparison to other trucks. If the cost at priority in the model then in this case Truck 1 is used for transportation of material/product because of its lower transportation cost other than two trucks. From the solution Table 15 shows that Truck 2 has moderate emission and transportation cost/rental fees. And it shows the mixed behavior of the assignment of truck.

Y_{1212}	7900			Y_{1312}	2500			

5. CONCLUSIONS

In this paper, the study has suggested a SC optimisation model by considering the sustainability issues. The model gives many insights in the management of sustainable supply chain. Multi objective GP has been used to handle numerous conflicting goals such as cost, carbon emission, embodied carbon footprint and trade credit. A compromised solution at satisfactory level can be achieved by solving the model. The suggested model quantifies the total cost, total carbon emission, embodied carbon footprint (indirect carbon emission) and trade credit in a SC by taking different types of trucks having different emission level. This model also provides information when to use a particular truck for the transportation of material in the SC.

Abstract: Despite the intensive research has been done in supply chain management (SCM) a little research has been done so far on this issue with respect to a single sector in India. This research in the field of Supply Chain Management is mainly concentrate on the impact of supply chain strategy (SCS) dimensions on Supply chain performance (SCP) in the supply chain .This research bridges the gap and deficiency on the research done previously in this issue and particularly about the Impact of Supply Chain Strategy on Supply Chain Performance. Hence, the main objective of this study is to find the influence of supply chain Strategies (SCS) on SCP. Furthermore, enhanced supply chain Strategies is directly related to improve supply chain performance. This research is based on Indian Automobile Industry which is the fasted growing and major contributor in GDP in India. The research find the Impact of Supply Chain Strategy on Supply Chain Performance based on their results, Fantasy et al. (2009) In his research he suggested that further investigating his research in a different geographical region. To widen understanding on this topic and to go after the recommendation of the preceding research, this research closely related to Fantasy et al. (2009) and this research done in the Indian automotive industries.

Keywords: Supply Chain Strategy (SCS), Supply Chain Performance (SCP)

1. INTRODUCTION

The economic growth of India which is developing country is typically dependent on its key industry and is key resources .The automobile industry in India in recent decade shown a momentous growth and established to be one of the one of the fastest growing and one of the strongest drivers of technology. Growth which generate employment (Gottschalk and Kalmbach, 2007). The new & emerging trends opens a new era in automobile industry for developing country like India (Choudhary and Goyal, 1997) after economic globalization the Indian automobile industry has got a remarkable market potential. Globalization creates a tremendous development in the field of technology especially in communications and transport. After 1991 due economical liberalization the GOI has made tremendous changes in economic policy which gives enormous opportunities for FDI to investments in the country. Post globalization the automobile industry in developing countries is experiencing a rapid transformation has made remarkable impacts on Indian economy. The automobile sector is one of the largest in the world. The industry accounts for 7.1 per cent of the country's Gross Domestic

Product (GDP). The Two Wheelers segment with about 81 per cent market share is the leader of the Indian automobile market owing to a growing middle class and a young population. Moreover, the increasing interest of the companies in the rural markets further aided the growth of the sector. The overall Passenger Vehicle (PV) segment has around 13 per cent market share.

From previous research it is clear that there is a definite correlation between implementation of effective and efficient Supply Chain Management (SCM) practices like Supply Chain Strategy and Supply chain Flexibility (Souresh Bhattacharya, Sunil Giri et al.2014) .Due to this the automotive industry in Indian is facing an interesting evolutionary phase and the automotive supply chain has a big role to play in this evolution. The supply chain strategy dimension like effective supply chain strategy, Customer satisfaction and minimization of cost connected with supply chain is the most important aspect for automobile industry. The most crucial aspect of this value chain is the complex system of SCM which incorporated with manufacturing .These vital dimensions of SCM (Strategy, Flexibility & performance) will provide free hand to business executive

to take decisions on SCM .With today's cutthroat competition and scarcity of resources the firm's must be optimal utilized to understand better application of SCM and thereby offer better value to customers and improve the performance of the organization (Chow et al., 2006). Currently Automobile industry in our country facing a challenge counterpart its supply chain standards with developed countries (Chang-Tai, H. et al 2009) and industry having a tremendous potential for integration of supply chains (Park, D.et al 2012) .The Indian automobile industry requires sustainable growth because its significant contribution towards GDP. The industry will developed a supply chain that can manage long term growth along with flexibility and much responsive which can handle any short term volatility. The industry on the stage of rapid changes in due to shorter product life cycle, new customers, product customization .This research is based on impact of major dimensions of supply chain strategy on the supply chain performance

2. LITERATURE REVIEW

Today's competitive market require effective and efficient supply chain strategies which are essential to construct competitiveness and make their position in the market so that companies can compete their competitors. Along with business strategies companies must think seriously supply chain strategy which is can build companies's position in competitive market.

Supply chain strategy is different for different product. Due to unique features of product companies requires definite supply chain strategies for that product. Companies can make their strategy as per supply and demand uncertainty, product life cycle and manufacturing complexity Due to these uncertainties diverse supply chain strategies emerged (H.L.Lee, 2002).Hence it is necessary that companies adopt the accurate SC strategy so that they can compete in the market. For taking leverage over competitors companies adopt customer oriented strategies such as customized logistics and agility which enhanced the demand while operational strategies and lean network enhanced supply side capabilities (E. A. Morash 2001) .Supply chain performance is a crucial and quickly developing area for researcher in supply chain management in current scenario. To conquer an efficient and effective supply chain, many

companies have realized the implication of performance evaluation and what measures should be used. The main goal of performance measurement are to improve the efficiency and effectiveness of a supply chain (Beamon 1999; Gunasekaran et al. 2001).The organizational performance refers to how well an organization acquire its market -oriented, financial goals in terms of performance items such as return on assets(ROA), market share and growth rate(Vickery et al. 1991). In supply chain performance cost, quality, response time and service quality level are the performance indicators (Christopher and Towill, 2001). Lippman (2001) recognized the effect of product cycle time, due date performance, cost and quality on operational performance.

The evaluate firm performance has been by in different manner by different researchers to assist firm in measuring their supply chain. There is number of problems in measurement of firm's performance (Richey et al. 2009). Firm performance include three different types of measurement for performance these are resources measurement, output measurement, and flexibility (Sukati et al. 2012).Recently supply chain performance is becoming area of research for many researcher. Reputed industries are trying to hard and finds the ways which can enhance performance of supply chain so that the can efficiently controlling their business activities.Companies concerned for their competition because market is shifting from individual company performance to supply chain performance. The whole chain's can be able to fulfill the end-customer's needs through product availability and responsive, on-time delivery.Traditional company boundaries are changing as companies find out new ways of working together to achieve the ultimate supply chain goal along with the ability to fill customer orders faster and more efficiently than the competition..

3. HYPOTHESES AND RESEARCH MODEL

This research find the impact of supply chain management strategy on supply chain performance which is based on the Canadian researchers.Which developed a model which show the theoretical relationship among, strategy, flexibility and performance. Figure 1 is simplified to show strategy performance connections in accordance with the suggested hypotheses by Fantazy *et al.* (2009).

Fig. 1. Basic Model (Fantazy et al. 2009)

Based on the research model Fantazy *et al.* (2009) in this research following hypotheses developed.

H1: Supply chain strategy have direct impact on the supply chain performance Dimensions.

H2: Deals with impact of adoption of proper Supply Chain Strategy on Supply Chain Performance.

H3: The overall total and indirect effects of Supply Chain Strategy on Supply Chain Performance

Research Model

Fig. 2. Research Model

4. RESEARCH METHODOLOGY

4.1 SAMPLING AND DATA COLLECTION

The data is collected from different methods that can be used for collecting data viz. using a survey strategy, such as structured observation, interviews and questionnaires (Saunders et al. 2007). In statistically testing the enormous amount of structured data needed from different respondent who fill the questionnaire. Hence large number of respondents that therefore should be contacted and the small information available from respondents, the questionnaire is selected to collect the data needed to test the above hypotheses (Cooper and Schindler 2003; Saunders et al. 2007). Besides this (Cooper and Schindler 2003)

- A questionnaire allows get in touch inaccessible contacts
- It is less costly (it costs less time and money to reach a large sample)
- A questionnaire is perceived as more unspecified
- It allows respondents to take time to think about the questions
- The data can easy be worked out used for analyzing and testing

Although a questionnaire is the most common choice to collect the data needed in this thesis, it has also some disadvantages

- No interviewer interference available for explanation;
- The questionnaire may not be too long, so the measurement items are limited;

This research is based on a quantitative approach, which was conducted on Indian automobile industries the data collection instrument used was a questionnaire which was sent to small and medium-sized automobile industries and ancillary industries within different supply chains. The data from 129 respondents are also classified by their job functions are corporate executive, purchasing, manufacturing/production, distribution/logistic, SCM, transportation, material, and operation from Indian automobile industries

4.2 RELIABILITY ANALYSIS

The Cronbach's alpha was conducted to assess the reliability of each item. Cronbach Alpha values over 0.7 indicate that all the date can be considered consistent (Nunally, 1978). For each of the item, factor analysis was used to reduce the total number of dimensions to controllable factor. Principal components analysis is used to extract factors with (eignevalue greater than 1) Varimax rotation is used for factor matrix. Sampling adequacy measurement tests are also examined via the Kaiser-Meyer-Olkin statistics to validate use of factor analysis.

Factors analysis showed that the KMO value of 0.81 indicate sampling adequacy. Factors analysis showed that the KMO value of 0.81 indicate sampling adequacy. The factor model for supply chain strategy indicates four distinct factors loading without any misclassification: innovative strategy (INS), customer satisfaction strategy (CSS), efficient supply chain strategy (ESCS), and agile supply chain strategy (ASCS). Cronbach's alphas among 14

items in the questionnaires exceeded 0.7. Four items are identified for innovative strategy (INS), four items identified for customer satisfaction strategy (CSS), two items are identified for efficient supply chain strategy (ESCS), and four items are identified for agile supply chain strategy (ASCS). These items are treated as independent variables. A similar factor analysis was applied to the supply chain Performance practices areas: cost performance (CP), logistic performance (LP) and customer satisfaction performance (CS). A total of 16 items were reduced to three factors loadings. Cronbach's alphas among 16 items in the

questionnaires are exceeded 0.7. Seven items are identified for: cost performance (CP), four items identified for logistic performance (LP) and five items are identified for customer satisfaction performance (CS). These items are treated as dependent variables. The KMO value of 0.78 indicate sampling adequacy

4.3 CORRELATION ANALYSIS

The correlation between independent variables (supply chain strategy) and dependent variables (supply chain performance) were shown in table 1

TABLE 1: Correlation Analysis

	Inovative Strategy	Customer Satisfaction Strategy	Efficient Supply Chain Strategy	Agile Supply Chain Strategy	Cost Performance	Logistic Performance	Quality Performance
Inovative Strategy	1						
Customer Satisfaction Strategy	.521**	1					
Efficient Supply Chain Strategy	.033	.244*	1				
Agile Supply Chain Strategy	-.049	.135	.651**	1			
Cost Performance	.117	.162	.431**	.462**	1		
Logistic Performance	-.133	.081	.326**	.564**	.567**	1	
Quality Performance	-.166	.218	.152	.518**	.292*	.499**	1

*p value <0.05, **p value <0.01

Result show that Innovative Strategy & Customer satisfaction strategy had no significant correlation with all three supply chain performance parameters but Efficient supply chain strategy had positive correlation with cost performance and logistic performance but it had no correlation with quality performance .Agile supply chain strategy had positive correlation with all three parameters of supply chain performance

4.4 REGRESSION ANALYSIS

The parameters of this model are estimated using multivariate regression analysis. Table 1 shows coefficients of each model along with corresponding test statistics. In Model 1 where the dependent variable is cost performance, the model seem to be reliable (p-value for F<0.01 and adjusted R-square of 0.259. Model 2, dependent variable is logistic performance. The model also seem to be reliable (p-value for F<0.01 and adjusted R-square of 0.581. Model 3, dependent variable is quality performance. Once again, the model also seem to be reliable (p-value for F<0.01), and adjusted R-square of 0.442.

TABLE 2: Model parameter estimates of supply chain orientation (t- Value in parenthesis)

	Model 1 Dependent variable = Cost performance (CP)	Model 2 Dependent variable = Logistic Performance(LP)	Model 3 Dependent variable = Customer Satisfaction (CS)
Constant	1.582	2.714	3.034
Innovative Strategy(INS)	0.156	-0.179	-0.372

	Model 1 Dependent variable = Cost performance (CP)	Model 2 Dependent variable = Logistic Performance(LP)	Model 3 Dependent variable = Customer Satisfaction (CS)
	(0.964)	(-1.238)	(-2.802)
Customer Satisfaction Strategy(CSS)	.000 (-0.002)	0.086 (0.794)	0.328 (3.281)
Efficient Supply Chain Strategy(ESCS)	0.148 (1.407)	-0.054 (-0.569)	-0.259 (-2.992)
Agile Supply Chain Strategy(ASCS)	0.300 (2.256)	0.510 (4.281)	0.604 (5.514)
Adj R²	0.259	0.581	0.442
F-Value	5.241	7.650	11.881

*p value <0.05, **p value <0.01

5. RESULTS

In current research, the following outcomes were obtained: The correlation analysis showed that innovative strategy is not related to supply chain performance parameters, while customer satisfaction strategy has very weak positive correlation with supply chain performance parameters. Agile supply chain strategy is significantly correlated related to supply chain cost performance and having weak correlation with logistic performance and customer satisfaction performance. Agile supply chain strategy significantly correlated to all supply chain performance. Finding show there is a weak relationship between supply chain management strategy and supply chain performance. Hypothesis 1 examine the impact of supply chain management strategy and supply chain performance and testing found that there is a little impact between supply chain management strategy and supply chain performance. Hypothesis 2 considered the adoption of proper strategy can improve supply chain performance. According to the result shown proper adoption of strategy effect supply chain performance. Hypothesis 3 show the overall impact of supply chain strategy results show that supply chain strategy effect on cost performance is less than that of logistic performance and customer satisfaction performance.

6. DISCUSSION AND IMPLICATIONS

The most important issue faced by organizations is identified and apply the best strategy to organizational practices. Research conclusion show that supply chain management strategy is the weak relationship to supply chain performance. Supply chain management strategy is key factors and being impact on supply chain performance. To efficiently managing the supply chain organizations need to agree to proper supply chain strategies into supply management chain practices (Sufian, 2010). Efficient supply chain management is vital aspect to building and sustaining competitive advantage in the market place. The

research hypotheses are tested by using multiple regression models. The result of this study may be contributes to the supply chain management knowledge in several ways. This study was to put in to the knowledge on supply chain management performance by finding the impact of supply chain management strategy & supply chain management performance.

7. LIMITATION AND FUTURE RESEARCH

There are a number of limitations of current research..

- This study limited only on automobile industry in India. From single-sector study is that the conclusions may not be generalizable to other sectors..
- The sample choice and size was based on a convenience sample, which is often used for exploratory work (Zikmund, 2003), rather than a random probability sample.
- The sample represented a limited number of companies in one sector only.
- The study is based on a questionnaire. Therefore, there is a possibility of respondents answering questions in their own opinion.

Abstract: Remanufacturing is the process of converting used and discarded products/ components/parts of equipment into the same as new condition. The aim of this paper is to develop an instrument and find the effect of critical success factors on performance measures for establishing remanufacturing. The effect of critical success factors on performance measures was giving the awareness for successful achievement of establishing the remanufacturing industry. This effect was supporting growth and achievement for remanufacturing industry. Based on an exploratory study of Indian organizations, remanufacturing factors and performance measures factors have been identified. This paper discussed the results of a survey on performance factors of the feasibility of remanufacturing in Indian manufacturing industries. The validation of this developed instrument through an artificial neural network.

Keywords: Critical Success Factors, Performance Measure Factors, ANN.

1. INTRODUCTION

The sustainable development has to save resources and improve the environment. Many industries across the world are engaged in a remanufacturing process to improve their performance improvement. The “6R” rule is the important to measure the goal. 6R rule consists of Reduce, Reuse, Recycle, Recover, Redesign and Remanufacture. Remanufacturing is one of the most active factors in “6R” rule. In remanufacturing, the parts are disassembled, cleaned and assessed for wear and breakage. Worn out, missing or not- functioning components are replaced with new components. The remanufacturing process takes place in a factory environment. It is organized as an industrial process so that it can benefit from the advantage of a series of production. These are a constant quality level and rationalization. Remanufacturing is the process of renovation used products makes sure that the quality of remanufactured products is equivalent to new products. Remanufacturing is the process of value recovery and reuse of used products. It has been accepted by the western world. Now, India is to take up as an organized industrial sector. The remanufacturing component is indicated 65% of the energy saved in the manufacture of the original product and preserved for the remanufactured product. These are energy and raw materials savings, economic contribution per unit of product; products are remanufactured and kept out of the waste stream longer. Landfill space perseveres, air pollution is reduced.

2. LITERATURE REVIEW

Winifred L. Ijomah *et al.*(1999) have described the remanufacturing evidence of environmentally conscious business practice in the U.K. Surendra M. Gupta and Hasan K. Aksoy (1999) explained an analytical model for remanufacturing systems. Geraldo Ferrer and Robert U. Ayres (2000) were suggested the impact of remanufacturing in the economy. Anstine J. (2000) has described the consumer’s willingness to pay for recycled content in plastic kitchen garbage bags as a hedonic price approach. Ali Rıza Motorcu and Abdul kadir Gullu (2006) were analyzed a statistical process control in machining, a case study for machine tool capability and process capability. Atul B. Borade and Satish V. Bansod (2007) were studied the domain of supply chain management. Bei L.T.and E.M.Simpsons (1995) has determined consumer purchase decision for recycled products. Bert Bras and Rick Hammond (1996) were described towards design for remanufacturing metrics for assessing re-manufacturability. Barr S, A Gilg (2001) was analyzed the factors influencing environmental attitudes and behaviors. B. Mahadevan *et al.* (2003) have reviewed the Periodic review, push inventory policies for remanufacturing. Barr S. (2007) was identified the factors influencing environmental attitudes and behaviors. Charles L. Goldey *et al.* (2004) were used remanufactured switching equipment to reduce restoration time in case of a disaster. Christos Zikopoulos and George Tagaras (2008) were investigated the attractiveness of sorting before disassembly in remanufacturing. Dewhurst P.

(1993) was designed the product for manufacture and disassembly. Donald and Lyons (2005) were analyzed the integrating waste, manufacturing, and industrial symbiosis. Kampan Mukherjee and Sandeep Mondal (2010) were analyzed some issues related to remanufacturing technology a case of an Indian company. Lund, Robert T., and Hauser, William M. (2010) studied on remanufacturing an American perspective. In (2011) an article published on remanufacturing in the automotive industry: challenges and limitations. In (2012) an article published on remanufacturing an answer to global warming. Henry Widera and Gunther Seliger (2015) have described the methodology for exploiting potentials of remanufacturing by reducing complexity for original equipment manufacturers. Rui Zhanga *et al.* (2015) have described a simulation based genetic algorithm approach for remanufacturing process planning and scheduling. Anjar Priyono, et.al (2015) has discussed the strategic operations framework for disassembly in remanufacturing. Sara J. Ridley and WL Ijomah (2015) have developed a novel pre-processing inspection methodology to enhance productivity in automotive product remanufacture. Ian Graham *et al.* (2015) have described the performance measurement and KPIs for remanufacturing. Euan Long *et al.* (2016) have analyzed the technical solutions to improve global sustainable management of waste electrical and electronic equipment (WEEE) in the EU and China. Harpreet Singh and Pramod Kumar Jain (2016) have concluded that remanufacturing of functional surfaces using developed ECH machine. Factors affecting for remanufacturing are

IF1- Top management involvement and commitment, IF2- Human resource management, IF3- Remanufacturing support system, IF4- Forward/reverse logistics system design, IF5- Remanufacturing process, IF6- Suppliers involvement for remanufacturing, IF7- Sustainable development practices. The literature review indicates wide variations in approach and definition of organization performance measures.

3. RESEARCH METHODOLOGY

This research paper is to identify and interpret the critical factors that affect remanufacturing and organizational performance and statistically validate if any correlation exists between them. The instrument developed for collecting the data contains 56 variables; twenty-two for remanufacturing process, eight for remanufacturing support system, six for sustainable development practices, six for forward/reverse logistics, six for human resource management, four for suppliers involvement and four for management. Figure 1 represents the test model that has been proposed for an Indian remanufacturing industry. To test the causal relationship multiple regression analysis was carried out. The main reason for employing multiple regressions is to determine the minimum number of a set of variables, which are most strongly related to the dependent variable and to estimate the percentage of variations in the dependent variable. The sample was collected from different industries. The continuous efforts by the authors and the support of the study organizations generated a 49.2% response rate, which was quite encouraging.

Fig. 1. The test research model

4. ANALYSIS AND RESULTS

Nunnally (1978) stated that an alpha value of 0.70 indicates a strong alpha value with consistent inter-item correlations. Since the alpha value for all the factors is found to be equal to or greater than 0.70, the scales developed here are judged to be reliable. Cronbach's alpha (Cronbach 1951) factor was calculated and is presented in table I. The coefficient was found to be 0.732, indicating that measures have a high degree of criterion-related validity when taken together.

TABLE 1: Reliability statistics of critical success factors

Cronbach's alpha	Cronbach's alpha based on standardized items	N of Items
0.730	0.732	56

4.1 Interpretation of factors affecting remanufacturing industry

This paper proposes described some of the problems facing for establishing remanufacturing industry. Critical Success Factors are described as an industrial point of view in India. Factor 1 accounting for 52.32% of the common variance is named as Top management involvement & commitment. Factor 2, accounting for 50.31% of the common variance is human resource management. The third factor accounts for 45.33% of common variance named as remanufacturing support system. The fourth factor accounts for 30.67% of common variance named as "remanufacturing process". The fifth factor accounts for 22.02% of common variance named as "forward/reverse logistics". The sixth factor accounts for 56.88% of common variance named as "suppliers involvement for remanufacturing" This factor involves suppliers' ISO series certification must for remanufacturing. Environmental partnership with suppliers and OEM's for remanufacturing. Suppliers training and involvement are required for remanufacturing. The seventh factor accounts for 55.97% of common variance named as "sustainable development practices".

4.2 Interpretation of factors affecting organizational performance

In the case of organizations performance measures, a five-factor models are considered. Factor1 accounts for 38.27% of common variance named as "financial performance".

Factor 2, accounts for 41.66% of common variance named as "productivity performance". Factor 3, accounts for 40.44% of common variance named as "remanufacturing quality performance". Factor 4, accounts for 32.08% of common variance named as "customers satisfaction". This is a very important factor which covers customer's complaints or claims about the remanufactured product. Factor 5, accounts for 48.77% of common variance named as "employees satisfaction". The factor involves employment generation through remanufacturing.

4.3. Remanufacturing performance model

Multiple regressions extend the concept of simple linear regression to cases where a researcher wishes to apply several explanatory variables in predicting the value of dependent variable. This analysis is adopted when the researcher has one dependent variable which is presumed to be a function of two or more independent variables the analysis concerning relationship is known as multiple correlations and the equation describing such relationship as the multiple regression equations. Table II shows the multiple regression analysis results remanufacturing factors and organizational performance measures. The remanufacturing performance model of the significant relationship between improvement approaches and performance indicators was developed. The proposed work involves exploratory research on remanufacturing industry. The factors are described some of the problems facing the remanufacturing industry.

4.3.1 Financial Performance model: In this model five input factors are incorporated out of seven input factors, however, the effect of each factor was assessed separately on the output of the model. The model is a financial performance model.

Financial Performance = $3.043 + 0.347 \times \text{Top Management Involvement and Commitment} + 0.279 \times \text{Remanufacturing Support System} + 0.260 \times \text{Suppliers Involvement for Remanufacturing} + 0.134 \times \text{Remanufacturing process} + 0.129 \times \text{Forward / Reverse Logistics} + 0.100 \times \text{Human Resource Management} + 0.117 \times \text{Sustainable development practices}$.

5. ARTIFICIAL NEURAL NETWORK

The following parameters are used for artificial neural network model formulation shown in table III. Figure 2 describes the process in artificial neural network.

TABLE 2: Multiple regression analysis results remanufacturing factors and organizational performance measures.

OPM IF ↓ →	Financial Performance	Productivity Performance	Remanufacturing Quality Performance	Employee Satisfaction	Customer Satisfaction
IF1	0.347	0.202	0.095	0.107	0.135
IF2	0.100	0.381	0.162	0.236	0.128

OPM IF ↓ →	Financial Performance	Productivity Performance	Remanufacturing Quality Performance	Employee Satisfaction	Customer Satisfaction
IF3	0.279	0.377	0.559	0.221	0.232

IF5	0.260	0.125	0.135	0.189	0.096
IF6	0.129	0.086	0.048	0.144	0.141
IF7	0.117	0.049	0.188	0.584	0.522
Intercept	3.043	1.109	1.007	1.006	1.178
Multiple R ²	0.750	0.868	0.778	0.823	0.776
F-value	4.947	10.881	5.125	9.360	11.776

TABLE 3: Details of ANN model formulation parameters.

Method	Multilayer perception
Minimum units in hidden layer	49 (Three times the total No. of factors)
Maximum units in hidden layer	56
Initial Lambda	0.0000005
Initial Sigma	0.00005
Interval offset	± 0.5
Minimum relative change in training error	0.0001
Minimum relative change in training error ratio	0.001
Software used	SPSS V 20

Fig. 2. Artificial neural network

ANN is a non-linear data-driven self-adaptive approach has shown that all the models have correctness of at least 90.4 % and above. The overall percent correctness of 91.9% is also very high. Table IV shows the percent correct prediction for performance measures. ANN is a tool for validation of structured model/ framework.

6. DISCUSSION AND CONCLUSION

In general, theory and models are needed to be developed and consolidated to establish the relationship between

critical success factors and performance factors. The paper is designed to address this gap in particular for the remanufacturing industry. The purpose of this paper is to understand the concept of remanufacturing in industrial sectors and to identify the critical factors and performance measures factors for manufacturing industries in India. The data was tested for normality test, reliability test, validity, adequacy test and internal consistency. The data cleared all these tests and was ready for analysis. Each CSF's of the model was examined and suitable measures were identified

to measure them. The explorative method was used for finalization the priority of CSFs. The various input and output parameters were grouped into seven and five factors respectively. The constitutions of these factors were confirmed by using an item to scale loading. The correlations between seven input factors and five output factors were obtained. The relations were obtained using multiple regression analysis. The relations were optimized using linear programming techniques. These optimized performance measure factors were integrated to form the model for remanufacturing industry. ANN is a non-linear data-driven self-adaptive approach which shows all the models have correctness. ANN is a tool for validation of structured model/ framework.

Ranking the Barriers of Food Supply Chain for Better Control over Food Safety

Shubham Dikshit, Ravi Kant

Department of Mechanical Engineering
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

Abstract: In present era, a significant number of people are getting affected because of consuming low-grade food. As a result, consumers are becoming more concerned about the food safety and quality of food products. This perception of consumers forces organization to work not only on quality but also on the food safety issues. This study is focused over identifying and prioritizing the barriers of food supply chain for food safety practices in food organization. Fuzzy DEMATEL approach is adopted in this study to distinguish cause and effect barriers of food supply chain for food safety practices. This study utilizes the fuzzy DEMATEL method which can recommend the most vital barriers having effect on other barriers. Fuzzy set theory deals with sources of indecision or vagueness that is ambiguous and non-statistical in nature.

Keyword: Fuzzy DEMATEL, Food Safety, Food Supply Chain, Food Supply Chain Barriers

1. INTRODUCTION

Food might be characterized as "safe" if it affirms perceived national/worldwide principles as far as its substance, showcase introduction and kind of distribution channel. Food safety covers precautions against all types of health threats directly or indirectly caused by foods (Giray and Özkan, 2012). A dangerous food item can occur at any link of food supply chain from beginning through planting, treating, gathering, preparing, transportation, retail, dissemination, stockpiling, dealing with, arrangement, and disposition. An effective sustenance items safety management can state food product situations, incidents, and outbreaks by nations (Boddie et. al. 2014). In food supply chain, producer has to face issues like seasonality in creation, weather factor, adulteration and use of chemical hazards, pressure of good quality raw materials and worth decay between various stations of supply chain. Because of these particular attributes of nourishment items, it is indispensable for industrial producers to contract providers to ensure the supply of crude materials as far as the correct volume, quality, place and time with keeping product safe to consume (Bloemhof et al., 2015). Consumers are more concerned about quality and safety of food. Food processing industries are at high pressure to follow environment policies and provide good as well as safe food to customer, at the same time keeping the profit maximized. Small and medium type organization generally ignores or show reluctance towards adapting food safety measures. Food safety implementation is affected by three factors production characteristics, organizational characteristics and employee characteristics (Ball et al. 2009). Adequate training and education with full management commitment will motivate workers to apply food safety implementation in organization. Due to globalization things consumer used

to eat decades ago have been replaced or modified, e-commencing has been entered in this field. These modifications also increase the risk of food safety. A large amount of harvested food gets wasted because of not having proper understanding and collaboration for food safety. The goal of this study is to identify the food supply chain barriers which loath the food safety practices in food supply chain and prioritization will be assigned to the barriers with application of fuzzy DEMETAL.

2. LITERATURE REVIEW

The extensive literature reviews were carried out related to Food Safety in food supply chain. The several papers were selected related to food safety and food supply chain related subjects. There are various concepts, conflicting definitions and overlapping views among the researchers and practitioners, but central theme is still the same for all of them. This study tried to find out different FSCBs, these authors dealt with while doing their research.

Due to emerging trends of globalization of food production a worldwide integrated system has been introduced for food production and distribution (Trienekens and Zuurbier, 2007). It is necessary to improve food safety practices, social standards, management behavior and involvement of government & public bodies etc. (Taylor Joanne, 2011). The role of government plays a vital role to achieve food safety at all level for that it is recommended that government should provide economic support to establish food safety mechanism in these firms and should support them to sustain such systems (Karaman et al., 2011). Lack of practical skill and knowledge, resistance to change, lack of funding and lack of understanding about issues influence food safety implementation in organization (Mensah and

Julien, 2011). Collaboration with suppliers and logistics service providers with them can significantly diminish risks and subsequently improve profits and lead to revenue growth (Chaudhuri A. et al., 2016). The food warning system is required to help managers of food manufacturing firms to identify food safety risk in advance (Wang and Yue, 2017). Arendt et al. (2015) find that there are eight motivators and ix barriers which affect food safety practices by employee. Different organizations suffer different problems regarding food safety implementation and it depends upon there the size of the organization. Poor food processing firm design is the result of lack of food safety practices and lack of justifiable practices (Hasnan et al., 2014).

Griffith et al. (2010) assess the food safety culture in food supply chain. A total of six possible groupings including: food safety management systems and style; food safety leadership; food safety communication; food safety commitment; food safety environment and risk perception were acknowledged as “culture” factors that could contribute to food safety performance. These can form the basis for evaluating food safety culture and how this may be done practically along with the creation of a positive food safety culture is discussed. Management is traditionally talked about in food safety but a distinction is drawn between this and food safety leadership.

TABLE 1: FSCB and References

Barrier code	Barriers Name	Description	Reference paper
FSCMB1	Lack of Top Management Commitment	Top management is not focusing on food safety and their commitment towards food safety is poor.	Ball et. al. (2008), Arpanutud et. al. (2009), Griffith et al. (2010), Mensah and Julien (2011) Taylor Joanne (2011),
FSCMB2	Lack of Clear Understanding of Food Safety Requirements	Not having proper understanding about the necessity of food safety practice for business.	Yepp and Fairman (2004), Arpanutud et. al. (2009), Taylor Joanne (2011),
FSCMB3	Lack of Motivation & Reward	Rewards are considered as one of the influencing factor for employee’s performance. Workers need to be appreciated and motivated to implement food safety as they are sole responsible for food safety implementation at ground-level.	Arpanutud et. al. (2009), Taylor Joanne (2011), Yepp and Fairman (2004), Griffith et al. (2010), Mensah and Julien (2011), Narayanamurthy and Gurumurthy (2015)
FSCMB4	Lack of Fund for Food Safety Implementation	Proper funding for food safety practices is necessary as food safety implementation requires a complete planning and infrastructure.	Arpanutud et. al. (2009), Yepp and Fairman (2004), Karaman et al. (2011), Miewald et. al. (2013), Hasnan et al. (2014)
FSCMB5	Lack of Food Safety Policy & Strategies Planning	Management need to strategically develop and plan various policies in such a way that it can be implemented at ground-level with ease.	AruomaOkezie I. (2006), Trienekens and Zuurbeir (2007), Miewald et. al. (2013), Arendt et al. (2015)
FSCMB6	Lack of Facilities & Equipment	Not having proper facilities and equipment will affect food safety practices.	Ball et. al. (2008), Mensah and Julien (2011), Arendt et al. (2015)
FSCMB7	Lack of strict Law Enforcement by the Government	It is necessary that apart from forming the rules, government need to make sure about their enforcement.	Yepp and Fairman (2004), Trienekens and Zuurbeir (2007), Arpanutud et. al. (2009), Mensah and Julien (2011), Taylor Joanne (2011)
FSCMB8	lack of Organizational Structure to Support Food Safety	Not having basic requirement for implementing food safety in organization.	Mensah and Julien (2011), Miewald et. al. (2013)

Barrier code	Barriers Name	Description	Reference paper
FSCMB9	Lack of Organizational Food Safety Methodologies	Organization need to adopt different methods for food safety which requires commitment towards food safety.	AruomaOkezie I. (2006), Griffith et al. (2010), Pedersen et al.(2016)
FSCMB10	Lack of Food Safety Practices	Employees are not willing to adopt predefine standard process of food safety in business processes.	Ahmed et al. (2005), Ball et. al. (2008), Arpanutud et. al. (2009), Griffith et al. (2010), Taylor Joanne (2011), Fahrion et al. (2013), Karaman et al. (2011)
FSCMB11	Lack of Training and Education	The action of teaching a person about importance of food safety and its necessity.	Ball et. al. (2008), York et al. (2009), Taylor Joanne (2011), Fahrion et al. (2013), Vieira Luciana Marques et al. (2013), Arendt et al. (2015)
FSCMB12	Poor Packing and Handling of Food Product	Packaging and handling are the technology of enclosing or protecting products for distribution, storage, sale, and also refers to the process of designing, evaluating, and producing packages.	Ahmed et al. (2005), Ball et. al. (2008), Arendt et al. (2015), Narayanamurthy and Gurumurthy (2015)
FSCMB13	Lack of Standard Format for Food Inspection	Step by step guidelines for the inspection.	Griffith et al. (2010), Shukla et al. (2014), Wang and Yue (2017)
FSCMB14	Lack of Benchmarking Practices	Benchmarking is comparing one's business processes and performance metrics to industry bests and best practices from other companies	Griffith et al. (2010), Mensah and Julien (2011), Moazzam et al. (2012)
FSCMB15	Lack of Performance Measures	The process of collecting, analysing and reporting information regarding the performance of an individual, group, organization, system or component.	Aramyan et al. (2007), Mensah and Julien (2011), Griffith et al. (2010),

Methodology:-This paper integrates the fuzzy sets and DEMATEL method to evaluate food supply chain barriers f. The next section discusses both methodologies.

Fuzzy Set:-A definite amount of fuzziness exists in terms of people's opinions, interpretation and perception. The theory intends to describe uncertain or fuzzy data in the environment. Instead of merging various skills, motivations, ideas and opinions of a specific or group decision maker, it is advisable to transform the linguistic terms into fuzzy numbers (Zadeh, 1965).. Human opinion generally described by equivocal language, like 'very low',

'low', 'medium', 'high' and 'very high'. The fuzzy set is express by the membership function. In this context, a triangular fuzzy number can be defined as a triplet $\tilde{A} = (l, m, r)$ where l, m and r denote lower, medium and upper numbers of the fuzzy sets and $l < m < r$. The membership function of a triangular fuzzy number can be expressed given below. It represents the grade of any element x of X that have the partial membership to A. The fuzzy set theory enables the membership functions to work over the range of real numbers [0, 1]. A fuzzy set comprises elements which have different degrees of membership in it.

TABLE 2: Definition and Membership Function Of Fuzzy

Fuzzy Number	Definition	Membership function (l, m, r)
0	Very low influence	(0, 0, 0.25)
1	Low influence	(0, 0.25, 0.5)
2	Medium influence	(0.25, 0.5, 0.75)
3	High influence	(0.5, 0.75, 1)
4	Very high influence	(0.75, 1, 1)

$$\tilde{A} = \{(x, \hat{u}(x))\} \quad X \in x$$

Where $\hat{u}$ is the membership function and $X = \{x\}$ represents a collection of elements x .

$$\hat{u} = \begin{cases} 0 & x < l \\ \frac{x-l}{m-l}, & l < x < m \\ \frac{r-x}{r-m}, & m < x < r \\ 0 & x > r \end{cases}$$

Fig. 4.1. Triangular Fuzzy Number

Fig. 4.2. Fuzzy Rating and Their Membership Function

Figure 4.1 shows a triangular fuzzy numbers. The equivalent relationship between the linguistic terms and triangular fuzzy numbers can be found out in accordance with Table 4.1. Consequently, fuzzy rating and their membership function are illustrated in Figure 4.2

This study utilizes the triangular fuzzy number for getting the ideal clarification from group decision making. Fuzzy linguistic variables deal with human response as a part of their language. Fuzzy aggregation processes must comprise a defuzzification step. The most commonly used method is Centroid method (Center-of-gravity method) (Yager and Filev, 1994). But this method is not able to distinguish two

different- shaped fuzzy numbers which can be converted into the same crisp number using Centroid method (Wu and Lee, 2007). Therefore, this paper employs CFCS (Converting Fuzzy data into Crisp Scores) proposed by Opricovic and Tzeng (2003) for de-fuzzification procedure.

According to the process of CFCS method (Opricovic and Tzeng, 2003), the left and right scores are first determined by fuzzy min and fuzzy max based on the fuzzy numbers obtained in the group evaluation phase. And then the final crisp score is calculated as a weighted average based on the membership function. The CFCS (Converting Fuzzy data into Crisp Scores) defuzzification method is appropriate for

the fuzzy aggregation process. The CFCS method gets a better crisp value (Chang et. al. 2011). According to membership functions, the total score can be found out as a weighted average mean the degree of criterion i that affects criterion j and fuzzy questionnaires n ($n = 1, 2, 3, \dots, h$). The CFCS method involves a five-step algorithm as follows.

Step 1. Normalization

$$xr_{ij}^n = (r_{ij}^n - \min l_{ij}^n) / \Delta_{min}^{max} \quad (1)$$

$$xm_{ij}^n = (m_{ij}^n - \min l_{ij}^n) / \Delta_{min}^{max} \quad (2)$$

$$xl_{ij}^n = (l_{ij}^n - \min l_{ij}^n) / \Delta_{min}^{max} \quad (3)$$

Where $\Delta_{min}^{max} = \max r_{ij}^n - \min l_{ij}^n$

Step 2. Evaluate the normalized value from right and left:

$$xrs_{ij}^n = xr_{ij}^n / (1 + xr_{ij}^n - xm_{ij}^n) \quad (4)$$

$$xls_{ij}^n = xm_{ij}^n / (1 + xm_{ij}^n - xl_{ij}^n) \quad (5)$$

Step 3. Evaluate total normalized crisp values:

$$x_{ij}^n = [xls_{ij}^n (1 - xls_{ij}^n) + xrs_{ij}^n \times xrs_{ij}^n] / [1 - xls_{ij}^n + xrs_{ij}^n] \quad (6)$$

Step 4. Evaluate crisp values:

$$Z_{ij}^n = \min l_{ij}^n + x_{ij}^n \times \Delta_{min}^{max} \quad (7)$$

Step 5. Integrate crisp value

$$Z_{ij} = \frac{1}{n} \sum_{n=1}^n Z_{ij}^n \quad (8)$$

4.2 DEMATEL Method

Decision-making trial and evaluation laboratory (DEMATEL) method was developed in Battelle memorial institute of Geneva by science and human affair program in between 1972 and 1976. The DEMATEL method is based on graph theory. It is a comprehensive method for building and analyzing a structural model involving causal relationship between complex barriers (Wu and Lee, 2007). The DEMATEL method differentiates barriers into cause and effect groups. Prioritization of barriers can be achieved by this method. The digraph portrays a basic concept of contextual relation among the elements of the system, in which the numeral represents the strength of influence. Hence, the DEMATEL method can convert the relationship between the causes and effects of factors into a comprehensible structural model of the system.

The steps of DEMATEL process summarized below:

Step 1. Construct the initial direct-relation matrix by the help expert's panel, and obtain the assessments about direct

impact between each pair of elements. Converting the linguistic assessments into crisp values, we obtain the direct-relation matrix $A = [a_{ij}]$

Where A is a $n \times n$ non-negative matrix, a_{ij} indicates the direct impact of factor i on factor j ; and when $i = j$, the diagonal elements $a_{ij} = 0$.

Step 2. Normalize the initial direct-relation matrix. The normalized direct-relation matrix $T = [t_{ij}]$ can be obtained through Eq. (4.9). All elements in matrix T are complying with $0 \leq t_{ij} \leq 1$, and all principal diagonal elements are equal to 0.

$$T = \frac{1}{\max(\max_{1 \leq j \leq n} \sum_{j=1}^n a_{ij})} A \quad (9)$$

All elements in matrix T are complying with $0 \leq t_{ij} \leq 1$, and all principal diagonal are equal to 0.

Step 3. Acquire the total-relation matrix S using the Eq. (4.10) in which I is an $n \times n$ identity matrix. The element s_{ij} indicates the indirect effects that factor i have on factor j , so the matrix S can reflect the total relationship between each pair of system factors.

$$S = T(1 - T)^{-1} \quad (10)$$

Where S is total- relation matrix

Step 4. Calculate the sum of rows and columns of matrix S . To make the conclusion more noticeable, we compute D_i and R_i through Eqs. (4.11) and (4.12) respectively. The sum of row i , which is denoted as D_i , represents all direct and indirect influence given by barrier i to all other barriers, and so D_i can be called the degree of influential impact. Similarly, the sum of column j , which is denoted as R_i can be called as the degree of influenced impact, since R_i summarizes both direct and indirect impact received by barrier j from all other barriers.

$$D_i = \sum_{1 \leq j \leq n} S_{ij} \quad j = (1, 2, 3, 4 \dots n) \quad (11)$$

$$R_i = \sum_{1 \leq i \leq n} S_{ij} \quad i = (1, 2, 3, 4 \dots n) \quad (12)$$

The D_i shows the total effects by the i^{th} barrier on the other barriers directly and indirectly. The R_i shows the total effects on the j^{th} barrier by other barriers directly and indirectly. The $D_i + R_i$ shows the cumulative of the effects on and by the i^{th} barrier on the whole system. The $D_i - R_i$ shows the net effect of i^{th} barrier on the system. If $D_i - R_i$ is positive then the i^{th} barrier will be the cause of the system and negative value will denote the net receiver.

Step 5. The priority weight can be given to the FSCBs by below:

$$W = \frac{\sum_{j=1}^n D_i + R_i}{\sum_{i=1}^n \sum_{j=1}^n D_i + R_i} \quad (13)$$

Case Study:-The organization A is public sector organization. It was established in 1965 and currently it has more than 26000 employees working allover India. The organization A consists of major department Procurement, Movement, Storage, Quality Control, Engineering, HR Activities Handle by Top Management. It is a government funded organization and not a profit making organisation. Subsidy is given by Govt. of India. The organization has ISO 9001:2000 certification. The organization A is engaged in procurement, storage and distribution of harvested food commodities.

Application of Fuzzy DEMATEL:- For this study, eight experts have been taken who has experience as well as knowledge in concern field

Step 1:- Identification of most vital barriers of food supply chain for food safety (FSCB) by literature review and by expert opinion.

Step 2:- Construct the initial direct-relation matrix by the help expert's panel, and obtain the assessments about direct impact between each pair of elements.

Step 4:- After getting normalized fuzzy direct-relation matrix, the fuzzy total relation matrix can be achieved by equation 9. The fuzzy total relation matrix is shown in Table 7

Step 5. The sum of rows and the sum of columns are separately denoted as D and R within the total-relation matrix S through the formulas given in equation 11 and equation 12. Sum of D+R will denote the cumulative impact on the system by the barrier whereas D-R will show the net impact of barrier on or by the system. By evaluating D+R and D-R cause and effect barriers can be identified.

Step 6. For prioritizing the barriers the summation of D+R will be divided to each barrier. Hence the weight of the barrier will be achieved. This weight will signify the importance of the barrier on food safety in food supply chain. To calculate weight, equation 13 will be referred.

3. FINDINGS AND DISCUSSION

By extensive literature review and expert discussion, Fifteen FSCBs have been identified. The inter-relations amid different barriers have been found out from academicians and a panel of industry experts. Food safety implementation is a duty for each and every food industry. To be competitive in market, organization should focus quality as well as safety of food product. Food safety implementation in organization restores the trust of customer about the safety of product which going to be consumed and hence ultimately increases the productivity. By applying fuzzy DEMATEL method weight priority is given to the FSCBs according to their impact on the system is evaluated. Fuzzy DEMATEL method is generally used to find inter-relationships among framework barriers, and visualizes this structure by cause-effect relationship diagram. D_i value of each barrier finds out by adding row value of the barrier which shows i^{th} barrier's impact on other barriers to achieve them and R_i signify the impact of other barriers over the i^{th} barrier. Prioritization is carried out by $D+R$ which signifies the cumulative influence of barrier on system.

Lack of clear understanding of food safety requirements and lack of top management commitment has given highest priority as their weights are 0.0724 and 0.0721 respectively. Lack of performance measure and lack of benchmarking practices are given third and fourth priorities with weights 0.0711 and 0.0687 respectively. Rest of the priority weights are mentioned in the Table 8.

4. CONCLUSIONS

Food safety in food supply chain refers to the range which covers preparation, handling, transporting, storage and serving of food such that it must be prevented to foodborne illness. This study is focused on evaluating the barriers of food supply chain for food safety implementation. Fuzzy DEMATEL method is implemented on the barriers to prioritize the FSCBs. The priority weight is evaluated in this method by calculating $D+R$ which signifies the cumulative influence of FSCB on the system. Lack of clear understanding of food safety requirements FSCB1 is most significant FSCB as it has weightage maximum with value 0.0724 and given first priority. The result suggested that it is management's responsibility to communicate the necessity of food safety implementation to the all the entities of food supply chain and for implementing the food safety in food supply chain management should be aware of food safety related issues and challenges. The organization should focus more on management commitment towards food safety implementation. Lack of top management commitment FSCB1, Lack performance measures FSCB15 has given top priority after lack Clear understanding of food

safety requirements FSCB2. The priority of other FSCB for food safety has given in Table 8.

The result of the study will help the policy makers and managers to understand the food safety issues in food supply chain and enable them to take better steps for minimizing the food loss either quantity wise or quality wise during the movement of food. Like other studies this research also suffers with limitation. In the prioritization of FSCB, proposed fuzzy DEMATEL rely upon limited number of experts. It is based on expert's knowledge and experience on food safety. Any biased opinion can influence the result. More number of experts can be consulted to get more accurate results.

Sustainability in Agri-Food Supply Chain

Man Mohan Siddh, Gunjan Soni, Rakesh Jain

Department of Mechanical Engineering
Malaviya National Institute of Technology, Jaipur, Rajasthan, India.

Abstract : This paper describing the challenges faced by agri-food industry for sustainability and the significant role of agri-food supply chains. Also discuss the practices for sustainable food supply chain likely characteristics of sustainable innovation for agri-food supply chain and in what way industries practicing higher levels of performance related to economic, social, and environmental perspective.

Keywords: Sustainability, agri-food supply chain, agri-food industry

1. INTRODUCTION

Today we have numerous organizations working all day and night to find out better ways of matching their operations and economic logics for the protection of resources which are of utmost importance for survival of human society. The new and better ways that are to be developed will have to be implemented cautiously keeping in mind their sustainability. A great number of studies done recently show that if we progress in same way as of now, considering the rate of depletion of resources and rate of increment of human population, we will run short of resources providing us food even with all industries combined.

The whole agri-food supply chain works through a complex system linked using many acting points known as actors. The major cause which is responsible for unsustainability in system is none other than this current and complex structure with many actors in it with conventional mind-set. Modern day supply chains, specially the food supply chains are the consequences of old system but with modern day organizations which tells us how most of them their design models on economic bases as the primary benchmark of growth and effectiveness. In order to satisfy their conventionally set targets most of them practice unsustainable methods. The history of organization and its management have been well documented (Piore&Sabel, 1984; Stout, 2012; Williamson, 1995). When an industry works with financial point of view as its base, they work with scale and leverage strategy. Scale and leverage are a by-product of the overriding concern for efficiency, productivity and shareholder wealth (Albert, 1993). For solution to current problems, Innovation can prove to be a boon for mankind. Companies will have to develop more sustainable consumption models. But two vital points need to be kept in mind while doing so-First of all, the companies need to shift their focus only from getting more value out of sustainable methods they are going to apply. Most solutions currently adopted are strategic remedies

rather logical solutions. They need to realise the important role they play as an organization in society. Coming to second issue, the innovation should be sustainable by itself and work effectively in long term rather than providing short term solutions. Moreover, the implementation of innovations should be supportive and done after analysing the sustainability problems in current agri-food supply chain.

2. CHALLENGES FACED BY AGRI-FOOD INDUSTRY FOR SUSTAINABILITY

Currently, the food industry has been going through unexperienced changes, thus, making it the most competitive industry thriving for sustainability in current scenario whether it's about share of production, consumption or employment. To give you an idea of this, here are some statistics –In Europe, food industry revenue is constituted by 14.5% of total manufacturing revenues, 15.5% of the employment and 12.5% of the value added in manufacturing. Also, the food industries which deal internationally here are small in number but with a wide range of products for sell. Another interesting fact is that 99% of the companies and 63% of the employment is accounted for by small and medium enterprises (SMEs). (ECSIP Consortium 2016; Fooddrink, Europe, 2015). In case of USA, the agricultural industries account for a total of 4.8% of the total GDP (stats as of 2014).

The mentioned figures show how highly competitive is Agri-Food Industry. The critical point here is that main producers or price takers i.e. farmers have a very little bargaining power and participation. Also not to forget that industry is largely dependent on natural environment. For example – Farming is one of the most primitive technologies which gives us most important products, all of which rely on the natural environment. Although, it largely involves using surface water and deep root in lands, we need to realize now that we have been doing more harm than good to Earth by our cultivation methods which

involve excessive use of fertilizers and chemical products in greed for better yield. (EU Standing Committee on Agriculture Research [SCAR], n.d). Among all the activities contributing in emission of Green House gases, 15-28% comes from Food Systems in developed countries. (Garnett, 2011). This in turn is leading to environmental instability which makes it an important concern to be resolved at the need of the hour.

Another challenge is a social issue. The rate at which human population is increasing, we are expected to cross 8 billion mark by 2030 and make it over 9 billion till it's 2050. (UN, 2013). Calculating our current production capabilities and our development rate, we will need 60% more global food supplies which is a serious matter as this is a tremendous amount. We need to know that around 33% of the food produced globally gets wasted; this number needs to reduce drastically if we need sustainable development and better future not only for Agri-Food Industry but also for whole human society. Social issues also revolve around the health of consumers. As per recent surveys, we have over 600 million obese people and 1.9 billion overweight people, which is a huge disappointment knowing that other than this category we also have people who waste their food when a considerable part of this world does not even have proper access to food resources.

On summing up in brief, we can conclude that Agri-Food Industry faces a total of three major challenges – First, Food production largely depends on environmental, human and physical resources. Second, Consumer awareness for food is a vital matter. The sooner we get aware of negative impacts of unsustainable methods used to grow food we consume; the better conditions will get. Third, Complex network of supply chain with different level actors in it needs to change. Conflicts will arise if only a few or one of the actors sticks to sustainable method when others are not capable of it.

3. SUPPLY CHAIN AND AGRI-FOOD INDUSTRY

Food we consume gets produced using complex processes. Involving industrialized and mass production processes with many diverse actors. We need sustainable development in order to use our resources efficiently. There are three types of sustainability that should be considered for utilising the resources:

Economic Sustainability: While developing sustainable methods in Supply Chain and Agri-Food Industry, we should remember the limitations of capital and invest accordingly. The new methods should not take a heavy toll on capital or take down an industry to loss, making it a non-appreciable idea.

Social Sustainability: Social Sustainability involves providing social equality for workers and not harming their social rights at work place.

Environmental Sustainability: The most important factor for any industry to continue in long term is to keep in mind the idea of environmental sustainability. The process adopted for manufacturing should be environment friendly and not cause a Water Pollution, Land Pollution or Noise Pollution.

The food sector was the first of its kind which required to develop better methods as a result of sustainability issues (Fritz & Schiefer, 2008) and the matter of concern is that we are still looking for innovative solutions for bringing sustainability in supply chain and agri-food industry for public welfare. Siddh, et al., (2015) discussed that sustainable development of perishable food supply chain is related to economic, social and environmental sustainability of supply chain.

4. PRACTICES FOR SUSTAINABLE FOOD SUPPLY CHAIN

The previous works in this section have shown that how sustainable development in food supply chain is possible by adopting the practices which aim at 'harm reduction' and those stuck to 'harm elimination' (Pagell & Shevchenko, 2014). The sustainable supply chains should be economically viable and not harm, or perhaps provide the aid to natural and social environment (Pagell & Wu, 2009). In order to achieve sustainability, we need to improvise on all three sustainability factors and this can be achieved in following manner –

Environmental Sustainability: This part of sustainability can be worked upon by conserving natural resources using practices such as reducing the consumption of natural resources, reducing the emissions into the air, land, and water, and preserve the soil along with biodiversity. We should also practice the three R's which are recycle, reduce and reuse as they can drastically reduce the amount of waste produced. We should also keep in mind the animal welfare which involves proper breeding conditions, thus eliminating the veil acts of cruelty, and promotes handling and housing of animals safely.

Social Sustainability: Social sustainability can be improvised though taking better measures in health and safety practices, securing human rights of every individual and adopting the practices which support welfare and development of community. Social sustainability promotes the idea of living a healthy lifestyle, proper education and realising the responsibility of consumption. Social sustainability at workplace is a vital aspect as well which can be achieved by employing females and giving them equal wages and opportunities as well. Also, the workplace should have a healthy atmosphere and hygienic conditions. Many organisations have already taken a step towards social sustainability with extra activities such as childcare and philanthropy.

Economic Sustainability: The first step in order to gain economic sustainability is by adopting fair trade practices. Root actors in supply chains should keep transparency in system with no abuse of power and use fair methods while keeping limited confidentiality. Ensuring fair trade practices will not only lead to proper distribution of profits but also monitor the working of whole chain in an ideal manner which in turn will lead to an increment in consumer awareness as these processes will result in establishment of fixed premium rates on every article.

5. SUSTAINABLE INNOVATION FOR AGRI-FOOD SUPPLY CHAIN

As we have thoroughly studied how supply chain in agri-food is going through unsustainable methods of production currently, we need to focus on proper utilisation of resources and adopt sustainable methods of production, as current methods are putting future development at risk. The only way to have sustainable methods in this field is through innovation. It is through innovation that we can enhance our sustainable effectiveness (Hansen, Grosse-Dunker, & Reichwald, 2009; Horn & Brem, 2013; Schaltegger & Wagner, 2011; Siddh, et al., 2017). We need innovation right from grass root level to the highest level, thus, revolutionising our whole current structure. Innovations have to range from developing better technologies and processes, crafting out goods and services in better ways and finally making swap in our present business models.

The above mentioned in approaches are important in order to take over the diverse challenges in sustainability dimensions. It can be concluded in this context that the above discussed practices, if applied, will bring up a better system than our traditional supply chain, also making it more transparent and easier to manage.

6. CONCLUSION

After the great inputs from many scholars and suggestions from many researchers, it is safe to conclude that if we do not adopt sustainable methods for supply chain in agri-food industries, we might end up facing the greatest famine of all time as a result of the rate at which our resources are depleting and our population is increasing. In order to avoid this problem, we need to adopt sustainable methods and improvise in Social, Economic and Environmental Sustainability. For sustainable method, s we need Innovation – a sustainability oriented innovation which will change our current supply chain system with a better one right from the lowest to the highest level. These changes are possible only through efforts of industries as well as through awareness in consumers. For this world to last long and have better future, we need to rise and realise the importance of our resources and work for their

conservation while we develop better and sustainable methods for the human life to thrive on this planet.

Sustainable Supply Chain Management in Thermal Power Sectors of India

Biswajit Suin¹, Jitendra Narayan Biswal², Suchismita Satapathy³, Jhunu Kumar⁴

^{1,3,4}School of Mechanical Engineering, KIIT University, Bhubaneswar, Odisha, India

²Department of Mechanical Engineering

C.V. Raman College of Engineering, Bhubaneswar, Odisha, India

Abstract: Rapid industrialization activities in developing countries like India, to meet the demand of its growing population has increased its energy needs manifold. This in turn has led to installation of huge number of coal-fired thermal power plants in India. More power plants has not only intensified environmental degradation but also increased logistics related emissions, waste production, non-disposability of byproducts. Implementation of Sustainable Supply Chain Management (SSCM) practices in power plants is influenced by a number of interrelated barriers that negatively affects SSCM implementation. This research attempts to explore potential barriers of SSCM. An attempt has been made to prioritize these barriers using Grey Relational Analysis. Lack of Coordination and Internal Population Issues emerge as the most important and least important barriers respectively. Prior knowledge of these barriers and their ranking will help the decision makers to develop suitable strategies that would enable the organizations to reduce their inhibiting impact on SSCM implementation.

1. INTRODUCTION

India depends on hydro-electric, thermal power, nuclear power and wind power industries to meet its energy demands. However, around 70% of total electricity is generated by thermal power sectors in India that use coal as fuel. It has been also estimated that this trend may continue for at least the next 30-40 years. The dependency on thermal power has increased environmental and social hazards significantly in India. Subsequently, thermal power industries (TPIs) are experiencing high pressure from new economic, energy saving and environmental regulations. So, thermal power industries are showing increased interest in adoption of Sustainable Development (SD) practices.

Sustainable development aims in carrying out industrial operations to improve their economic, social and environmental performance (Hussain, 2011). Sustainability concepts in the supply chain has led to the emergence of sustainable supply chain management (SSCM) that emphasizes on management of economic, social and environmental footprints of the organizations as well as encouragement of good governance practices, throughout the lifecycles of goods and services (Grzybowska, 2012). Though, significant growth in SSCM adoption rate has been observed in developed countries, yet Indian industries particularly, TPIs don't share the same enthusiasm. This could be due to their lack of knowledge regarding various influential factors of SSCM, particularly the barriers of SSCM adoption. Hence, attempt has been made in this research to identify various Parameters that hinder SSCM adoption in Indian thermal power industries. Knowledge of these barriers will help the decision makers to formulate proactive strategies to minimize their impact.

2. LITERATURE REVIEW

Growing consciousness regarding environmental and societal issues has triggered one of the greatest revolutions in human thought, uniting the entire world in a fight against the emissions which are produced during industrial activities (Dubey et al., 2015). Particularly the last decade has seen an increased pressure to broaden the accountability of the industries beyond economic performance, for shareholders to sustainability performance, for all stake holders (Labuschagne et al., 2005). Consequently an increased interest was exhibited by organizations in addressing sustainability in their supply chains, which has been described as Sustainable Supply Chain Management (SSCM) that incorporates the triple bottom line of sustainability (Walker and Jones, 2012). Green or environmental aspect of SSCM focuses on minimization of the adverse environmental consequences of various activities of supply chains whereas the second one, social aspect of SSCM ensures ethical as well as decent working conditions of various stakeholders including the suppliers. The third component of the SSCM, the economic aspects ensures local economic generation through purchasing from local suppliers (Walker and Jones, 2012).

3. METHODOLOGY

To determine the most influential barriers causing hindrance in the implementation of SSCM, a standard questionnaire was designed consisting of 28 barriers in the context of Indian thermal power sector. A survey was conducted by sending the questionnaire by mail and personal contacts to different experts, managers, and employees of thermal power industries. The survey was conducted by using likert scale 1 to 5, (i.e, 1= totally

disagree, 2 = partially disagree, 3 = No opinion, 4 = partially agree, 5 = totally agree). The survey responses were analyzed statistically using SPSS to test the reliability and validity. Principal component factor analysis of the survey responses using varimax rotation extracted 10 important barriers. Grey relational analysis (GRA) is implemented to rank these barriers of SSCM in thermal power industries.

4. RESULT AND DISCUSSION

Multi-criteria decision making analysis is used in solving real life decision-making complex problems. Grey Analysis is a fantastic tool for the determination of ranks when the number of criteria and alternatives is countless large. Another important advantage of GRA is its ability to generate satisfactory outcomes using a relatively lesser amount of information (Rajesh and Ravi, 2015) Hence, Grey relational analysis has been employed in this research to rank the identified barriers mentioned below.

1. Resource Limitation
2. Lack of Performance Management Measures
3. Internal Population Issues
4. Operational Issues
5. Lack of Coordination
6. Legislative Issues
7. Lack of Eco-Literacy among Supply Chain Partners
8. Demanding Requirement from NGO's
9. Global Aspects
10. Unacquainted Society

Step-1: Generation of Grey Relations

In a multi attribute decision making (MADM) problem different attributes might require different units for measurement of their performance. Further, certain performance attributes might have a very large range. In addition, existence of attributes having different goals and directions also lead to incorrect results in the analysis (Huang and Liao, 2003). GRA addresses these issues by generating grey relational, where all performance values for each alternative is processed into a comparability sequence, in a process analogous to normalization (Kuo et al., 2008).

For a MADM, if there are m alternatives and n attributes, the ith alternative can be expressed as $Y_i = (y_{i1}, y_{i2}, \dots, y_{ij}, \dots, y_{in})$, where y_{ij} is the performance value of attribute j of alternative i. The term Y_i can be translated into the comparability sequence $X_i = (x_{i1}, x_{i2}, \dots, x_{ij}, \dots, x_{in})$, by use of one of equations 1, 2 or 3.

$$x_{ij} = [y_{ij} - \min \{y_{ij}, i=1, 2, \dots, m\}] / [\max \{y_{ij}, i=1, 2, \dots, m\} - \min \{y_{ij}, i=1, 2, \dots, m\}]$$

$$\text{For } i = 1, 2, \dots, m; j = 1, 2, \dots, n \quad (1)$$

$$x_{ij} = [\max \{y_{ij}, i=1, 2, \dots, m\} - y_{ij}] / [\max \{y_{ij}, i=1, 2, \dots, m\} - \min \{y_{ij}, i=1, 2, \dots, m\}]$$

$$\text{For } i = 1, 2, \dots, m; j = 1, 2, \dots, n \quad (2)$$

$$x_{ij} = 1 - \frac{|y_{ij} - y_j^*|}{\max\{y_{ij}, i=1, 2, \dots, m\} - y_{ij}^*, y_{ij}^* - \min\{y_{ij}, i=1, 2, \dots, m\}}}$$

$$\text{For } i = 1, 2, \dots, m; j = 1, 2, \dots, n \quad (3)$$

The generated grey relation values are shown in Table1

TABLE 1: Grey Relational Analysis

Barrier	Values
1	0.791667
2	0.944444
3	0.736111
4	0.930556
5	1
6	0.791667
7	0.763889
8	0.986111
9	0.805556
10	0.930556

Step-2: Determination of Grey Relational Coefficient:

Scaling of the comparability sequence values into the range [0, 1] is done in this step, shown in table 2. The alternative with larger value of X_i (equal to unity) is assumed to have highest strength. However, chances of existence of such kind of performance attributes are nil. Hence a reference sequence X_0 whose values are equal to 1, is defined and compared with the generated sequence (Tiwari et al., 2014). The reference sequence is expressed as follows.

$$X_0 = (x_{01}, x_{02}, x_{03}, \dots, x_{0j}, \dots, x_{0n}) = (1, 1, \dots, 1, \dots, 1)$$

$$(X_{oj}, X_{ij}) = [\Delta_{\min} + \xi \Delta_{\max}] / [\Delta_{ij} + \xi \Delta_{\max}]$$

$$\text{For } i = 1, 2, \dots, m; j = 1, 2, \dots, n \quad (4)$$

$$\Delta_{ij} = |X_{oj} - X_{ij}|; X_{oj} = 1$$

$$\Delta_{\min} = \min \{\Delta_{ij}, i=1, 2, \dots, m; j=1, 2, \dots, n\}$$

$$\Delta_{\max} = \max \{\Delta_{ij}, i=1, 2, \dots, m; j=1, 2, \dots, n\}$$

$$\xi = \text{distinguishing coefficient} \in [0, 1]$$

In our case $\xi = 0.5$

TABLE 2: Grey Relational Coefficient

Barrier	Values
1	0.395834
2	0.472222
3	0.368056
4	0.465278
5	0.5
6	0.395834
7	0.381945
8	0.493056
9	0.402778
10	0.465278

Step-3: Finding Grey Relational Grade:

In order to find grey relational Grade, the equation is given as

$$\Gamma(X_0, X_i) = \sum_{j=1}^m W_j \times (X_{0j}, X_{ij}) \text{ For } i=1, 2, \dots, m \quad (5)$$

Step-4: Ranking of Barriers

The ranks of all the Barriers were found out and grey relational grades & their ranks are shown in Table 3.

TABLE 3: Grey relational grades and corresponding ranks (Assuming, 'W' as unity)

Barrier	Values	Rank
1	0.395834	6
2	0.472222	3
3	0.368056	8
4	0.465278	4
5	0.5	1
6	0.395834	6
7	0.381945	7
8	0.493056	2
9	0.402778	5
10	0.465278	4

5. CONCLUSION

The implementation of SSCM is a complex and difficult phenomena, owing to its dependency on several factors. Hence, an attempt has been made in this paper to identify

potential factors those influence SSCM implementation in thermal power plants negatively. Through review of literature and questionnaire based survey 10 such factors were identified which were termed as barriers. Further, Grey relational analysis was used to analyze the inhibiting impact of these barriers and rank them according to their degree of negative impact on SSCM implementation. Lack of Coordination has been identified as the most significant barrier whereas Internal Population Issues as the least significant barrier. Prioritization of the barriers will give an insight to the decision makers to solve SSCM implementation problem in thermal power sectors.

³Department of Mechanical Engineering, Yashwantrao Chavan College of Engineering, Nagpur, Maharashtra, India.

Abstract: India is witnessing the exponential growth in vehicle population due to growth in economy, higher incomes, changing lifestyles and easy finance schemes. With increasing population of vehicles the number of End-of-Life Vehicles (ELVs) is also growing. ELVs are mainly recycled by semiformal sector in country. This sector uses primitive methods to recycle ELVs that result in low product recovery, environmental pollution and poses serious threats to human health. This sector has its own strengths and weaknesses. Promoting strengths and working against weaknesses can contribute in the development of sustainable end of life vehicle recycling industry. This paper identifies the problems being faced by the end of life vehicle recycling sector in India and the potentials through SWOT (strengths, weaknesses, opportunities and threats) analysis.

Keywords: ELV recycling, SWOT, India

1. INTRODUCTION

Automobile industry is one of the biggest industries in India and currently witnessing exponential growth in vehicle manufacturing. The factors behind this growth are improved economy, higher incomes, easily available finance and changing lifestyles (Chaturvedi, Chaturvedi and Short, 2012). India is emerging as a fastest growing passenger car market and second largest two wheeler manufacturers in the world. The country produces 13 lakhs passenger vehicles, 4 lakhs commercial vehicles, 76 lakhs two wheelers and around 3 lakhs tractors annually (Automotive Mission plan 2006-16). With the increase in number of new vehicles, the population of End-of-Life Vehicles (ELVs) is also increasing.

An end of life vehicle (ELV) is a specified vehicle which is discarded or is to be discarded by its registered owner as a waste (Go et al, 2011). ELVs are mainly classified as natural ELVs and premature ELVs. Natural ELVs means those vehicles whose life is over due to age and premature ELVs are those whose life have come to end due to unnatural reasons such as an accident, fire, and flood or vandalism damage. As per report of Ministry of Environment, Forest and Climate change (2016) around 9 million vehicles retired in 2015 and more than 20 million will retired by 2025. Figure 1 (a) and (b) Shows the different types of vehicle which will complete their useful life by 2015 and 2025 respectively.

Fig. 1. (a). ELV generation in India by 2015

Fig. 1 (b). ELV generation in India by 2025

End-of-Life Vehicle recycling has become a global issue due to economic and environmental reasons. Dismantler/recycler can earn profit by reuse/recycling the valuable parts present in ELVs. ELVs also contain hazardous substances such as waste oil, lubricants, lead acid batteries, air bags and coolants (Chen, Huang and Lian, 2010). If not properly recycled or disposed, these substances may have negative impact on human health and environment.

2. ELV RECYCLING PRACTICES IN INDIA

In India, ELV recycling is carried out by small units in semiformal sector. These units dismantle/recycle the ELV in a haphazard and unscientific manner. This results in low product recovery, environmental pollution and poses serious threats to the health of the employees. Dismantlers/recyclers are interested only in economic gains and do not follow any environmental laws. The ELVs are de-polluted at dismantling units. De-pollution involves removal of engine oils, coolants and lubricants. The drained engine oils are sold to small informal refineries. After de-pollution, the parts/components are removed from ELVs (refer fig 2).

Fig 2. End of life vehicle dismantling

The reusable parts/components are sold to scrap dealer. The non-reusable parts are sent for material recycling. The non-reusable and non-recyclable parts are dumped in an uncontrolled and unregulated fashion (Chaturvedi, Chaturvedi and Short, 2012).

3. SWOT ANALYSIS

SWOT analysis is one of the most straightforward methods used in the analysis of company or industry. The SWOT analysis identifies the strengths, weaknesses, opportunities and threats (Zhang and Chen, 2013). The SWOT analysis on the ELV recycling industry in India will be presented in the following section.

3.1 Strengths

3.1.1 Large number of ELVs

ELV population in India is continuously growing. It is estimated that total ELV generation in country will touch to 20 million by 2025 (Ministry of Environment, Forest and Climate change, 2016). The large number of ELVs indicates sufficient raw material for the recycling industry which is a positive factor.

3.1.2. Employment

ELV recycling business provides job to lakhs of people. It is estimated that more than one lakh families are employed in dismantling and recycling business directly (Mohan Ram, 2012).

3.1.3. Low labor cost

ELV dismantling requires extensive labor. In India, ELVs are manually dismantled in dismantling units. Low labor cost is the main advantage for the development of ELV recycling industry.

3.2 Weaknesses

3.2.1 Lack of ELV legislations/policies

In developed countries like Europe and Japan, ELV legislations play very important role in the development of ELV recycling industry. These legislations commonly set the target of 95% (in terms of weight) recovery of ELVs (Sakai, 2014). At present, India does not have ELV specific legislations/policies to regulate the haphazard and unhygienic recycling practices and to motivate manufacturers to design environmentally friendly vehicles. There is an urgent need to have legislations/policies to reduce environmental pollution and improve the vehicle recovery rate (Mohan Ram, 2012).

3.2.2 Lack of adequate infrastructure and technology

Country does not have bigger storage, dismantling and shredding facilities. The vehicle recycling units are small and they do not have capability and capacity to deal with bigger number of vehicles. ELV recycling businesses lack technologies to identify, separate and recover quality materials (Sivakumar, Barnabas and Anatharam, 2014). These units are not equipped to handle systems like airbags and seat restraints. Country needs to upgrade the infrastructure and develop technologies to deal with more number of ELVs in future.

3.2.3. Absence of manufacturer in ELV recycling

In India, manufacturers do not participate in ELV recycling. There is no co-operation between manufacturers and dismantlers. They do not provide dismantling information or training to the employees of dismantling units. Lack of dismantling information causes difficulty in ELV dismantling, low recovery and increase labor cost. To increase the dismantling efficiency and improve the recovery rate, manufacturers should design the vehicles for recycling and share the vehicle related information with the dismantlers and recyclers.

3.2.4. Low environmental awareness

Environmental awareness of India people is relatively poor. Knowingly or unknowingly everyone is polluting the environment. They are not aware of benefits of ELV recycling. There is a need to enhance environmental awareness through school education, newspaper and seminars and conferences. (Mohan Ram, 2012).

3.3 Opportunities

3.3.1. Efficient and viable ELV recycling industry

Current ELV recycling practices in India causes serious environmental pollution and loss of natural resources. With proper planning, co-operation among the government, manufacturers, recyclers, dismantlers and consumers,

country has a good opportunity to establish modern, efficient and viable ELV recycling industry.

3.3.2. Conserve natural resources

Environmentally friendly recycling and disposal of ELVs not only avoid the negative impact on the environment but also reduce the consumption of natural resources (Chen, Huang and Lian, 2010). It has been estimated that India can recover 2 million tons of steel, 1, 80, 000 tons of aluminum, 75, 000 tons each of rubber and plastic and some other material by 2020 (Mohan Ram, 2012). This will definitely reduce the consumption rate of primary materials and save the energy.

3.3.3 Preserve foreign exchange

Automobile recycling preserves foreign exchange (Mohan Ram, 2012). Due to economic development, the demand for raw material is consistently growing. Every year steel makers in India imports more than 5 million tons of scrap for recycling into finished steel. The scrap recovered from the ELV recycling will help to reduce the import of scrap and save foreign exchange.

3.4 Threats

3.4.1. Haphazard and unhygienic recycling process:

The dismantling/recycling unit uses primitive methods which are very unhygienic and poses serious threats to environment and human health (Garg, Sharma and Gangacharyula, 2014). Precious materials are not recovered in an environmentally friendly way and non-usable and non-recyclable parts are dumped in uncontrolled and unregulated fashion (Sharma et al, 2016). For example, Copper is recovered by burning of insulation which results in release of dioxins into the atmosphere.

3.4.2 Recycling units in residential areas

Most of the recycling units are located in the residential areas like Mayapuri in Delhi, Puda Pet in Chennai, Shivaji market in Bangalore and Loharchawl and Chor bazaar in Mumbai (Report on End-of-Life Vehicles Worldwide, 2012). Most of these units do not follow decontamination procedure. The hazardous fluids are spilled and disposed on the ground. The working area in unit is contaminated with oil, coolants and other fluids. This affects the health of employees as well as nearby residents. To avoid this, it is necessary to relocate these recycling units away from the residential areas.

3.4.3. Uncertainty about policy implementation

The implementation of policies influences the development of industry. Existing environmental laws and regulations have not been performed effectively. The implementation

of proposed policies is an important challenge for the development of ELV recycling industry.

3.4.4 Lack of efforts in designing green vehicles

ELV recycling rate and level of difficulties in dismantling are directly related to design of vehicles. These factors should be considered while designing the vehicles. Unfortunately, manufacturers in India have shown very little interest in designing the vehicles for recycling (DFR) and design for assembly (DFA).

4. CONCLUSION

Mature ELV recycling industry has not yet established in India. ELV recycling is presently carried out by semiformal sector. Haphazard and unhygienic recycling practices lead to environmental pollution and low recovery. Country does not have ELV legislation to regulate the recycling practices. Manufacturers neither participate in ELV recycling nor do they co-operate with recycling operators. The ELV recycling industry in India lacks adequate infrastructure and advance technologies.

The ELV legislations/policies in developed countries like Europe, Japan and South Korea have a significant impact on the world. India needs to learn from the experiences of these countries in the establishment of sustainable ELV recycling industry. Country need to develop strategies to encourage environmentally friendly ELV recycling practices, upgrade infrastructure and develop technologies. An efforts are needed to improve the consumer awareness through school education, print and electronic media and by conducting seminars and training programs.

Abstract: A long and discontinuous Supply Chain (SC), inadequate policy support, inefficient information and Knowledge Flows have constrained manufacturing development in the past in India. Now a day, a very crucial objective for any organization is to keep uninterrupted supply of required products, at right time and place. Manufacturing companies achieve global operations through various strategic business alliances including joint ventures and outsourcing, etc. SC has assumed a leading operations strategy position in manufacturing over the past 10 years. While dealing with the global competition, organisations realize efficient knowledge management has been identified as one of the key requirements for effective SC. Therefore, primary objective of this study is to determine penetration of knowledge flow in the Indian manufacturing organisations using survey method.

Keyword: Supply Chain, Knowledge Flow, Survey Method

1. INTRODUCTION

The slow pace of growth in the manufacturing sector at this stage of India's development is not an acceptable outcome. Therefore, to increase exports as well as provide its internal market with domestically produced manufactured goods that compete with imports, India must manufacture a much larger volume of products at competitive costs and quality. While dealing with the global competition, organisations realize efficient knowledge management has been identified as one of the key requirements for effective SC (Liu et al., 2013). The shape of global manufacturing SCs has changed dramatically with the application of computers and telecommunications (Planning Commission, Government of India).

The success of knowledge flow implementation is totally depend upon the successful implementation of SCKFEs and this research is focused on Indian manufacturing organizations. It is necessary to identify the level of penetration of implementation of SCKFEs in Indian manufacturing organizations. So an attempt is made through this study to assess the level of penetration using a survey of Indian manufacturing organizations.

The survey is executed through a well-designed and validated instrument in conformance with the objectives. Through a well-developed and validated Instrument/Questionnaire, in total 269 responses were collected from industries. The level of penetration of SCKFEs is determined by using descriptive statistics through analysis of collected responses. For each item the mean and standard deviation is calculated.

2. LITERATURE REVIEW

Gathering of knowledge from different sources is not easy and its spread among individuals, organizations and SC members is even more complex. Knowledge flow enablers can help to reduce the problems associated with the knowledge flow adoption in SC (Kurtz et al., 2012). Knowledge is recognized as an important source of competitive advantage and hence there has been increasing academic and practitioner interest in understanding and identifying the enablers that contribute to effective knowledge flow between SC actors. These factors are called as SCKFEs (He et al., 2013). This study identified 21 (see Table 1) SCKFEs through literature review, and in consultation with experts it has been categorised into four different categories namely "characteristics of knowledge flow", "strategic", "knowledge flow mechanism" and "organisational".

TABLE 1: List of SCKFEs

Enablers	References

3. INSTRUMENT/QUESTIONNAIRE DEVELOPMENT

A well designed and validated instrument/questionnaire is required to determine the level of penetration of knowledge flow in SC for Indian manufacturing organizations. This section elaborates that how to develop an instrument/questionnaire for the above stated objective. This instrument/questionnaire has two sections and was designed to collect detailed information about, the profile of respondents and organizations (14 Questions), Penetration of SCKFEs (21). Five point Likert scale is selected for scaling responses, as it is a psychometric scale which is generally involved in research that uses instrument/questionnaires.

A survey instrument/questionnaire was developed in order to test the research model. After framing the instrument/questionnaire it was pretested from the same industry experts and academia. A pilot study was conducted with 34 manufacturing organizations. Data collected from 34 organizations were tested for mean, standard deviation, missing data, kurtosis and skewness and found within the range. Hence all the measurement items were kept as it is for large scale data collection.

4. LARGE SCALE DATA COLLECTION METHODOLOGY

The survey was confined to India only and the data collection took six months. The survey was conducted in two modes. The offline mode preferred for the industries which are within the reach. The 350 printed questionnaires were distributed to industries with cover letter indicating the purpose and significance of the study. Out of 350 questionnaires the 62 respondents are completed the questionnaire and return back. This represents a response rate of 17.71% (calculated as 62/350). The survey was also conducted by the web-based method. The web base questionnaire with the cover letter indicating the purpose and significance of the study was emailed to 700 target respondents along with web-link (<http://goo.gl/forms/xmL6nECPkO>). To encourage response, follow-up emails and telephone calls were made to non-respondents after we sent out the questionnaires. Finally, we received 219 returned questionnaires, twelve of which were incomplete and thus discarded. A total of 207 completed questionnaires provided the study with a response rate of approximately 29.57%. The total 269 are responses collected by offline survey and web based survey. One of the concerns of the survey research is that the information collected from respondents might have a non-response bias. The test for non-response bias was executed to check for any significant difference between the early and late respondent (the difference between early and late is three months) considering the late respondent as non-respondents. The results of the independent sample t test showed no significant difference between two response waves ($p > 0.05$). Thus, it can be summarized that the non-response bias is not a cause for concern. The one way ANOVA test was carried out to check for any significant difference for type of organization (automobile, machine tools/equipments, electrical/electronics, process and FMCG), job position of respondents (senior management level, middle management level and lower management level) and found no significant difference at $p > 0.05$. In addition, a Harman's one-factor test was conducted because the data were collected from a single type of respondent at a single point in time.

5. DATA ANALYSIS

The collected data through developed instrument/questionnaire was analysed by using statistical package for the social science (SPSS) software. The descriptive statistics analysis has been done to analyse this data. The descriptive analysis displays univariate summary statistics for several variables in a single table and calculates standardized values and can be ordered by the size of their means (in ascending or descending order). By sorting the means in ascending order, the level of SCKFEs and vital enablers implemented in organizations were identified. The

implementation status of each enabler base on mean score is again validated from the panel of industry experts.

5.1 Characteristics of Knowledge Flow

The penetration of 'characteristics of knowledge flow' is moderately implemented in Indian manufacturing organization. The mean for this practice is 4.01 and very low standard deviation of 0.82. Now a day in implementation of knowledge flow in SC characteristics of knowledge flow play an important role. The characteristic of knowledge flow improves the quality and understandability of knowledge. The mean and standard deviation values of each SDA are given as follows (see Table 6.1).

TABLE 2: Descriptive statistics for characteristics of knowledge flow

Sr. No.	Item Description	Mean	Std. Deviation
1	Transferability of knowledge	3.94	0.81
2	Updated knowledge	4.07	0.75
3	Validated knowledge	4.04	0.92
		4.01	0.82

5.2 Strategic Enabler

The penetration of 'strategic enabler' is high in implementation of knowledge flow in SC for Indian manufacturing organization. The mean for this category is 3.95 and standard deviation of 0.74. The strategic enabler presents number of knowledge flow plans which positively influencing SC performance and competitiveness. Every manufacturing organization should work for the sharing of knowledge and improve SC performance. The mean and standard deviation values are shown as follows (see Table 2.4).

TABLE 3: Descriptive statistics for strategic enabler

Sr. No.	Enabler	Mean	Std. Deviation
1	Top management support	4.10	0.74
2	Strategic planning	4.04	0.77
3	Integration of knowledge	4.16	0.75
4	KF methodology	3.71	0.78
5	Relative power	3.84	0.65
6	The motivation of source and recipient firms	3.87	0.76
		3.95	0.74

5.3 Knowledge Flow Mechanism

The penetration of 'knowledge flow mechanism' is reasonable in implementation of knowledge flow in SC in Indian manufacturing organization. The mean for this category of knowledge flow mechanism is 3.98 and standard deviation of 0.82 (see Table 6.3). Every organisation should have some kind of mechanism (e.g. information technology infrastructure or regular meetings to support the storing, sharing and utilization of knowledge among employees), facilities (e.g. conference rooms or open access areas for informal gathering or dialogues).

TABLE 4: Descriptive statistics for knowledge flow mechanism

Sr. No.	Enabler	Mean	Std. Deviation
1	Strategic relationship	3.84	0.83
2	Employee training and site observation	4.05	0.75
3	Continuous communication	4.22	0.73
4	Personalization	3.90	0.77
5	IT infrastructure	3.91	0.96
6	Codification	3.94	0.86
		3.98	0.82

5.4 Organizational Enabler

The penetration of 'organizational enabler' is also moderately penetrated in implementation of knowledge flow in SC for Indian manufacturing organization. The mean for this practice is 3.97 and standard deviation of 0.81 (see Table 6.5). Organizational enablers are the vision and knowledge, the relationship and resources, and the culture of the organization that will need to do to develop and implement its strategy. Organisational knowledge reflects the view of how resources should be used in order for the firm to benefit.

TABLE 5: Descriptive statistics for organizational enabler

Sr. No.	Enabler	Mean	Std. Deviation
1	Collaborative alliance	3.81	0.79
2	Organizational culture	3.96	0.77
3	Common language and terminology	3.94	0.85
4	Organization's reputation	3.97	0.85
5	SC partners goals	3.86	0.73
6	Supply chain structure	4.26	0.84
		3.97	0.81

6. CONCLUSION

This study also checked the status of level of penetration of SCKFEs in Indian manufacturing organizations. The data of 269 respondents were collected through an instrument/questionnaire and it is analyzed by using statistical package for social science (SPSS). The descriptive statistics is used to represent the level of penetration of SDAs in Indian Manufacturing Organizations. The current study could provide an insightful understanding of the penetration of SCKFEs in the Indian manufacturing organisations. This is considered as a vital contribution since after all, the ultimate aim of management is to improve firm performance. The identified SCKFEs in different set will be useful to the SC managers and knowledge management executives for implementing knowledge flow in SC. These sets of SCKFEs will definitely assist them in understanding the SCKFEs and their effect.

² Principal, D. J. Sanghvi College of Engineering, University of Mumbai, India

Abstract: In today's competitive environment, industries are experiencing an increased pressure to reduce cost, improve quality and reduced delivery time to sustain in the market place. Hence, they have narrowed down focusing on the factors of their sustainability and other influencing factors, in such a way that the environmental concerns are ignored. Many actions of this underlying issue in the industries is restrained due to economic reasons, and hence there is a need to show necessary guidance and proof of economic benefits that would help in the broader application of the concept, such as Green Supply Chain Management (GSCM). In this context, there is a need to also spread awareness of GSM Practices. This study has been an attempt to review the extant literature to understand the benefits of GSCM and also to provide for a generic framework to measure the organizational performance. In this context, few hypotheses are conceptualized and proposed, which could be tested in the future.

Keywords: GSCM, Qualitative benefits, Quantitative benefits, Motivations, Economic performance, Environmental Performance, Operational Performance

1. INTRODUCTION

Environmental concerns nowadays are leading to new customer requirements, beyond conventional functionalities such as, quality and cost, while relating to how products are made, how long they last, and how they can be disposed of (Peattie, 1999). Environmental pollution has been a serious problem, and one of the major sources of emission is toxic gases from the manufacturing industries. To overcome this problem and to reduce the environmental pollution, manufacturing industries are required to incorporate the concept of "Green" in their supply chain". Srivastva (2007) defined: Green Supply Chain Management (GSCM) as integrating environmental thinking into supply-chain management, including product design, material sourcing & selection, manufacturing processes, delivery of the final product to the consumers as well as end-of-life management of the product after its useful life. Winroth (2009) stated that Green Supply Chain aims at continuous improvement of industrial processes and products to reduce or prevent pollution to air, water and land. Richards (1994) identified Green manufacturing as one that meets the customer demands for environmentally sound products, development of recycling schemes, minimizing the materials use and selecting the materials causing low environmental impact. Environmental concerns may also emerge due to their suppliers and in turn trouble the company's environmental performance and thus greening of the supply chain will help companies avoiding and controlling the potential challenge.

The reason for commitment to the greening of SCM was due to the environmental impacts of production. Hence the perspective changed from greening as a burden to greening as a potential source of competitive advantage in business (V. D. R. Guide Jr., L. N., 2002). The aim of this study has been to explore the benefits of green practices and to identify the organizational performance parameters.

2. LITERATURE REVIEW

There are different practices of GSCM involved internally as well as externally by organizations to add into account for the development of the country's economy, especially in countries like India. Karthik Kudroli (2014) has concluded three major types in this connection.

1. Less power and paper consumption termed as internal environment management practice.
2. Developing suppliers to practice green purchasing termed as external GSCM practice.
3. Waste minimization, investment recovery and environmental requirements after cooperating with the customers.

Any energy saving measure can be termed as green measure and such energy saving measure in the supply chain can be defined as GSCM. Manufacturers are responsible for the entire product life cycle right from its

origin to its disposal. According to VinodSambarani (2016), they have an important role to play in enabling green manufacturing by the use of waste free and emission free energy sources through which they can provide products to green consumers, who respond to global warming and climate change.

3. ACTIVITIES IN GSCM

Ninlawan et al. (2010) had done a study on Green Implementation on electronics industries, wherein they proposed activities of GSCM. These activities comprise of all the processes in GSC, starting from green procurement to green manufacturing to green distribution, till the recycle and waste management of the product.

3.1 Green Design of Product and Processes

Green Design deals with design for waste minimization (Srivatava 2007). The main social objective of Green Design is to ensure the sustainable society in regard with the available resources and ecological health. Hendrickson et al. (2001) suggested that the concept of green design mainly focusses on three goals for sustainable future: 1) Reduce or minimize the use of non-renewable resources 2) Manage renewable resources to ensure sustainability and 3) Reducing or eliminating the toxic and other harmful emissions to the environment, including emissions contributing to the environment.

3.2 Life Cycle Assessment (LCA)

In this technique the environmental effects and resources needed for development of new product or process are clearly traced out from the raw material supplier to the manufacturer and further to its disposal. LCA draws a boundary for eliminating or stopping the growth of inventory emissions and resources (Hendrickson et al. 2001). Gungor & Gupta (1999) described the LCA as a process of evaluating the environmental, occupational health and the resource related with the consequences of a product through all phases of its life.

3.3 Green Procurement

Green procurement is defined as eco-friendly purchasing, which involves activities like reduction, reuse and recycling of materials in the process of purchasing. It involves integration of environmental issues into purchasing decisions based on price, performance and quality. Elements of Green procurement programs are:

1. Recycled content products
2. Energy efficient products and energy efficient standby power devices
3. Alternative fuel vehicles, alternative fuels and fuel efficient vehicles
4. Bio based products And

5. Environmental protection priority chemicals

These elements help in selecting the product for the manufacturing process.

3.4 Supplier Selection

For effective GSCM, it is important that the materials and parts are purchased only from Green partners. The supplier who controls hazardous substances in the industries and has obtained green certificate can be considered as an efficient supplier (Ninlawan et al. 2010).

3.5 Green manufacturing

It is defined as the production processes, which use inputs with relatively low environmental impacts and they are highly efficient and generate little or no waste or pollution. Winroth (2009) stated that green manufacturing aims at continuous improvements of industrial processes and products to reduce or prevent pollution to air, water and land. The challenges associated with green manufacturing are meeting the customer demand for environmentally sound products, development of recycling schemes, minimizing the material use and selecting the materials that have low environmental impact (Richards 1994). Green manufacturing can lead to lower the raw material cost, increase the production efficiency and reduce the environmental and occupational safety expenses. The power consumption can also be reduced to a greater extent by implementing green manufacturing processes. It enhances environmental consciousness through 3 Rs (reduce, reuse and recycle) activities (Zhu 2007). Green manufacturing relies on a long term thinking, because the environmental impact created by industries has been there for many years and hence a sudden change will cause more investment on their capital, but if a longer time frame is considered, it is accountable. When a proper organizational approach is established the initial step of choosing options for green manufacturing is making an inventory by production operation of inputs used and the waste generated. The inputs used may be energy, raw materials and water. The waste generated includes off-specification products, solid wastes and inputs returned to their suppliers (Atlas & Florida 1998). They also stated that the other non-product outputs are sent to recycling treatment or discharged into the environment. The second step of choosing the option for green manufacturing process is selecting the important non product output and focussing on the waste streams in the product (Florida 1998). The third step proposed by Florida was generating the options to reduce the non-product outputs at their origin. These options are product changes, process change, input change, increased internal reuse of wastes and better housekeeping. These options are then evaluated for their environmental advantage, technical feasibility and employee & employer accessibility. These evaluations lead to improvement

mainly into two different categories, which are housekeeping and input changes.

3.6 Remanufacture and Refurbishment

Actually before sending the product to recycling, the manufacturer has the option to see whether the product can be repaired or reconditioned by either substituting the parts of the item or by making cosmetic changes, so that it can be sold in the secondary market as reconditioned or remanufactured goods.

3.7 Green Distribution

Shalishali (2009) classified green distribution as green packaging and green logistics. The transport characteristics of the product are influenced by factors like size, shape and materials, which have an impact on distribution. To overcome these impacts, a better packaging along with rearranged loading patterns could be used to increase the space and reduce the amount of handling.

3.8 Green packaging

According to Ninlawan (2010), green packaging can be practised by using green packaging materials, promoting recycling & reuse programs and cooperate with the vendor to standardize the packaging.

3.9 Green logistics

Jiang (2008) defined green logistics as producing and distributing goods in a sustainable way and the activities include measuring the environmental impact of different distribution strategies, reduction in energy usage for logistic activities, reducing waste and managing its treatment. The system integrates with traffic and transportation, storage & delivery, management & supervision and information flow.

3.10 Reverse logistics

Rogers & Tibben –Lemke (1998) defined reverse logistics as the process of planning, implementing and controlling the efficient, cost effective flow of raw materials in-process inventory, finished goods and related information from the point of consumption to the point of origin for the purpose of recapturing value or disposal. All the activities that a company carries out to collect the used, damaged, unwanted or outdated products as well as packaging and shipping materials from the end user or reseller could be considered as reverse logistic activities. Once the product has been returned to the company, the firm has multiple options to choose like resell, sell via outlet, salvage, recondition, refurbish, remanufacture, reclaim materials, recycle or landfill.

3.11 Waste management of product and processes

Waste management is an effect directed approach towards nature because it tries to reduce the landfills and

incineration of waste materials (Shalishali 2009). The collection, transportation, composting, recycling and disposal along with regulating and monitoring form a solid waste management system. Reuse is an important method of handling waste. It promotes the use of something again in its original form for the same or different purpose. Recycling is the process of reprocessing the used material to make a new product through physical, chemical or biological method. Recovery is the use of processed recyclable material as feed stock for industrial activities from waste. The energy released from this waste is used for generating steam or electricity.

4. MOTIVES FOR GSCM

The GSCM can be practised in the organizations through several internal and external drivers. New Zealand Business Council for Sustainable Development described, in their practical guide for business: guide to sustainable supply chain (2003), that supply chain is mainly focussed on three areas, such as 1) Improving the performance of business's own operations 2) Ensuring that the goods and services provided by the suppliers are sustainable and working with suppliers increases the efficiency and competitiveness and 3) Working effectively with customers and sales channel to design sustainable products and services. On against the backdrop of these general trends, the companies mainly rely on the motivation factors, which are classified as primary and secondary motivations.

Primary Motivations mentioned are:

Internal motivations and possible effects	External Motivations and possible effects
Risk Management • Supply interruption • Long term risk to human and environment • Competitive advantage Regulatory stance • Desire to go beyond compliance • Suppliers knowingly or unknowingly provide problematic substances • Supplier non-compliance poses production risk	• Enhanced brand image • Corporate culture of forecasting trends and moving proactively • Potential for harm to public image for environmental concern • International Purchasing Restrictions • Ecolabeling and product take back gaining momentum • May drive the creation of system for collection • Frequently focussed on high profile brands, transport, disassembly or recycling • Customer pressure • Often appear in conjunction with a threat to brand image • Regularly focusing on high profile brands

Source:

Secondary Motivations, such as 1) Cost reduction as suppliers apply pollution prevention 2) Enhanced quality and 3) Increased motivation, can result from supplier participation in new product development.

5. ENVIRONMENTAL AND ECONOMIC BENEFITS OF GSCM

According to the study performed by Lefebvre et al. (2000) on SMEs in Canada, implementing green strategies into the organization can help in improving the organizational innovativeness i.e. product, process and managerial innovation can be improved. According to them, the organizational competitiveness (cost containment, liability management and export performance) can also be developed. Zhu et al. (2007) mentioned that EMS such as GSCM has a positive relationship on the organizational economic performance. Sangwan KS (2011) differentiated them into qualitative and quantitative benefits such as:

Qualitative Benefits	Quantitative benefits
- improved working condition - Better organisation in public - Improved staff morale - Enhanced customer loyalty/ satisfaction - Establishing or improving brand value - Lowered regulatory concerns - Increased market opportunities - Improved product performance - Decreased liabilities	- Waste related - Reduced waste handling cost - Lowered waste categorization cost - Reduced waste treatment cost - Reduced waste disposal cost - Reduced waste storage cost - Life cycle related - Lowered transportation cost - Decreased packaging cost - Lowered cost of production - Low maintenance cost - Reduced overall cost of organization

6. ORGANIZATIONAL PERFORMANCE

Performance is a measure for assessing the degree of a corporation's objective attainment (Daft, 1995). Corporations adopting GSCM practices may generate environmental and business performances (Walton, et al., 1998; Zhu and Cote, 2004). A green supply chain, for example, can improve environmental performance (reducing waste and emissions as well as increasing environmental commitment) and competitiveness (improving product quality, increasing efficiency, enhancing productivity and cutting cost), thereby further affecting the economic performance (new marketing opportunities and increasing product price, profit margin,

market share and sale volume; (Purba, 2002). According to Walton, et al. (1998), Zhu and Cote (2004) and Purba (2002), as well as other experts, organizational performance measure is considered to include both environmental and financial performance.

Hypothesis

Keeping the global scenario in mind and seeing the way our environment is being impacted as well as considering the insights obtained from the extant literature, we feel GSCM practices are in a critical position to influence a country's carbon footprint. There exists a vast scope in developing countries, such as in India to adopt GSCM practices and thereby achieve organizational excellence. Small scale and medium scale manufacturing industries in India contributes largely to, and play a vital role in, the Indian economy. Therefore, we have laid our focus in assessing GSCM practices of Indian SMEs and have further hypothesised as follows:

H1: ENVIRONMENTAL PERFORMANCE HAS A POSITIVE RELATIONSHIP WITH GSCM PRACTICES IN SME MANUFACTURING FIRMS.

H1a: Reduction in business wastage improves environmental performance of manufacturing firms.

H1b: Environmental emissions directly impact environmental performance of manufacturing firms.

H1c: A firm's green image positively influences environmental performance.

H1d: Government involvement in GSC initiatives has a positive influence on willingness of SMEs to participate in GSC initiatives, thereby promoting environmental performance.

Construct definition: Business wastages are considered as hazardous & toxic material output, solid & liquid wastes, total flow quantity of scrap and percentage of materials remanufactured. Emissions are air emission and energy consumption. Green image of a company is enhanced by participating/organizing fairs or symposiums related to environmentally conscious manufacturing. The above hypotheses are proposed, based on the findings of (Zhu and Sarkis, 2006), (Hall, 2000), (Sarkis, 1998), (Hui, et al., 2001), (Gottberg, et al., 2006), (Hervani, et al., 2005), (Sarkar and Mohapatra, 2006), (Sheth and Sharma, 1997; Cannon and Homburg, 2001), (Doonan, et al., 2005), (Papadopoulos and Giama, 2007), (Tsoufas and Pappis, 2006), (Carter and Carter, 1998; Walker et al., 2008; Large and Thomsen, 2011; Buyukozkan and Cifci, 2012), (Lu et al., 2007; Hitchcock, 2012).

H2: GSCM practices have a positive influence on economic performance of SME manufacturing firms.

H2a: Environmental cost and efficiency have a direct and a positive relationship with economic performance.

H2b: Environmental revenues directly influence the economic performance.

H2c: Governmental regulations directly influence the economic performance.

Construct definition: Environmental cost and efficiency are cost of purchasing environmentally friendly products, cost of scrap/ rework, disposal cost, operating expenses, overhead expenses, fines & penalties and manufacturing cost. Environmental revenues are revenues from green products, recycling revenues and cost avoidance from environmental action. The above hypotheses are proposed, based on the findings of (Zhu et al., 2005; Azevedo et al., 2011; Green et al., 2012), Kumar et al. (2012), Koh et al. (2012), (Carter and Carter, 1998; Walker et al., 2008; Large and Thomsen, 2011; Buyukozkan and Cifci, 2012), (Lu et al., 2007; Hitchcock, 2012), Rajkumari Mittal., S. g. (2013).

H3: GSCM practices have a positive influence on operational performance of SME manufacturing firms

H3a: Customer satisfaction has a positive influence on operational performance.

H3b: Product delivery & time directly and positively impacts operational performance.

H3c: Inventory levels have a direct relationship with operational performance.

H3d: Product quality positively influences the operational performance

Construct definition: Customer satisfaction deals with after sales service efficiency, out of stock ratio and rates of customer complaints. Product delivery and time are delivery reliability, on time delivery, responsiveness to urgent deliveries, cycle time and delivery lead time. Inventory levels are level of safety stocks and order to ship. Product quality is customer reject rate and inplant defect fall out rate. The above hypotheses are proposed, based on the findings of (Papadopoulos and Giama, 2007), (Sarkis, 2003), (Tsoufas and Pappis, 2006), Buyukozkan and Cifci (2012), Sangwan K S (2011), Zhu, Sarkis, Kee-hung Lai, (2007), Rajkumari Mittal., S. g. (2013).

H4: Government initiatives impacts relationship between GSCM practices and business performance

Government involvement in GSC initiatives include direct technical and financial support, indirect encouragement with tax cut incentives and development of infrastructure for environmentally friendly industrial complexes (Su- Yol Lee). Globally, Governments are more involved in GSC practices as more emphasis is now laid on life cycle of products than pollution controls at manufacturing plants. Noci and Vergandi (1999) claimed that governmental support and regulations are more important triggers for environmental innovations in SMEs. R P Mohanty (2014)

reported that the external pressures of government regulations lead to GSCM practices.

7. CONCLUSION

It has been found from the extant literature that the major barriers to GSCM implementation is the unwillingness to change and the threat of incurring huge costs without getting proper returns. In this specific context, the proposed hypotheses are expected to help us in the measurement of the performance of GSCM practices in India. It shall additionally throw light on the level of maturity of GSCM practices and setting up of environmental goals. Thus, GSCM implementation can be eased by establishing clearly and communicating the benefits, cost and risk reduction to the top management or decision makers of SMEs in India.

Abstract : Companies planned their supply chain to save fiscal costs incurred in supply chain, hence as of now most of the companies having a tendency to locate their warehouses in each state. Hence they are supposed to pay tax as per state taxation policy when they move goods, and tax will not be refunded when you sell item from state to state, due to this reason companies used to set-up their own warehouses in each state to take the cost leverage. This is post GST scenario but implementation of GST companies will get tax credit even they move their goods from one state to another state. The GST law 2017 is simultaneously address both issues of the dual governance structure of the state and central bodies which leads to inefficiencies and many loopholes in the system. Also, the comprehensive effect of the multi layered taxes leads to higher taxes. The implementation of GST from 1 July 2017 will make the supply chain more efficient & effective and at the same time Logistics, outsourcing, distribution and warehousing is going to see a major transformation near future.

Keywords: Goods services and tax, Supply Chain, Logistics

1. INTRODUCTION

GOODS AND SERVICES TAX:

Due to complexities of the old tax system in India in near future the implementation of GST seems to be the biggest game changer for Indian taxation system. The old taxation system includes many taxes, many outdated rules and many legislations that can take up too much time and effort. Goods and services tax is an indirect tax this tax is imposed on manufacturing of product, sale of any goods and consumption of goods and services provided by service industry. This new tax system will replace the tax collected by the central and state governments. In this system tax collected during the purchase or sale of goods is independent of the state where the purchase or sale takes place.

The tax structure proposed by GST concile and the government pass the GST Bill or The Constitution (One Hundred and Twenty Second Amendment) Bill from the both houses of parliament. The tax rate under GST are 0 %, 5 %, 12 %, 18 % and 28 % this would be lower, however, there would be an increase in the number of assesses which come under the umbrella of GST. The increased number of assesses is expected to make up for the reduced tax and the overall tax collection is expected to increase but at the same time initially implementation create some problems to the

businesses. Some of the best GST systems across the world like Singapore and New Zealand use single GST, but India has opted for a dual GST model. The change in tax structure is expected to have a huge impact in supply chain in India.

2. SUPPLY CHAIN MANAGEMENT

Supply Chain Management Means -To managing efficiently the flow of goods and services and to control the movement and storage of raw materials, work-in-process inventory, and finished goods from point of origin to point of consumption. Now a days E - Commerce is fast growing market, The management of supply chain is totally mandatory for all organization. Without managing supply chain efficiently and effectively you have no idea to start or grow any business. Supply Chain Management (SCM) or commonly we can say Logistics is the crucial part of any business related to goods or services.

Supply chain is not only take care of material, information and finance that move through the process, from supplier to manufacturer to whole seller to retailer to customer but its ultimate aim to achieve achieve JIT (Just-in-time), inventory optimization, reduce cost and provide prompt service to the customer so as to increase profit.

Fig. 1. Impact of Supply Chain

Supply chain management involves the flow of materials between various parties that is-

1. Supplier to Manufacturer.
2. Manufacturer to Wholesaler.
3. Wholesaler to Retailer.
4. Retailer to Consumer.

There are 3 main flows of the supply chain: –

1. Product Flow.
2. Information Flow.
3. Finances Flow.

Supply chain is a complete network which creates the link between the producer and the customers. There is plenty of scope in supply chain management field especially in India. You would be surprise to know that India's inefficient supply chain results in an approximate loss of \$65bn per year (data from 2016). The statics show that around 13 percent of GDP in india constitute by supply chain costs which is more than 1.5 times of the percentage of developed countries. In the US, supply chain costs amount to 9 percent of the GDP. 65% of logistics in India moves by road and time spent at interstate check posts due to difference in taxes between states accounts to idle time (60% of total journey time) which will get eliminated in GST regime. Hence, transport time would reduce by 30-40% and transport costs by 20-30% leading to fall in prices by 3-4%.

3. IMPACT OF GST ON SUPPLY CHAIN MANAGEMENT

Supply chain is not only constitute the material, information and finance that move through the processes, from supplier to manufacturer to whole seller to retailer to customer but its ultimate aim is to achieve JIT (Just-in-time), inventory

optimization and reduce cost. In present system there are an array of taxes like excise duty, VAT, CST, etc. which levied at each level and added to the whole value known as Tax Cascading. GST will make it simpler and easier by contributing to a lower cost of production as tax at each level will be charged only on the value addition to an item. The major drawback of present indirect tax regime is the absence of tax credit will be eliminating by allowing unrestrictive tax credit under GST.

Before implementation of GST the thinking of industries is to keep warehouses and C&F agents at every state to avoid tax credit unavailability but post GST regime they rethink and this new system will provide industries the freedom to restructure their supply chain network. The new GST regime will once again better the situation by unifying the Indian market and facilitating a smoother flow of goods within the country. Even though border checkpoints may still exist for some time, the minor scrutiny at these checkpoints will greatly reduce transport hassles.

Goods and Service Tax is an attempt by our government to simplify and streamline our taxes, facilitate market growth and increase the revenue for our government by increasing its tax base.

The supply chain structure is gretely influenced by differential taxes based on geographical location. By eliminating multiple state taxes, the logistics companies are optimistic and consolidate their warehouses instead of maintaining one in each state to avoid central tax. This in effect brings the overall cost of the product down as the inventory cost and inventory carrying cost down. This frankly affects the final cost of the product brings the selling price down. The cost saved by the companies as a result of GST can be used to invest further to improve serviceability. The following are the major driving Factors of Supply Chain:

- Sale goods within a state

- Minimize tax liability.
- Procurement of Raw Materials, Packing Material, Consumables in a most tax effective manner to reduce Landed Cost
- Maximize Post Tax Return
- Maximize Value Addition in Supply Chain

After GST implementation, the design of the supply chain depends on customer service and logistics cost. It also offers flexibility into demand and supply. GST would also facilitate firms to increase the accuracy of the forecast. Small and medium size warehouses can also be merged into one bigger warehouse and by this companies can optimize their space requirement. Before GST trucks are idle for about 40% of the total travel time due to Central Sales Tax/Octroi payment. But due to GST implementation the time taken at various check posts while transporting goods will come down, which will, in turn, reduce costs and customers and logistics companies will get goods at shorter time which makes industries more efficient and profitable in the near future. Supply will also be able to match demand to a large extent.

The following are the benefits to the industry post GST implementation:

- Interstate transactions.
- Negotiation of price
- Better quality
- Improved forecasting
- Optimum inventory management
- Better trade-off between cost and customer service
- Capacity expansion
- Manufacturing flexibility
- It matches the demand and supply flexibility.
- Avoid unnecessary stock movement through states..

4. CONCLUSION

The implementation of GST in India will definitely make supply chains more efficient and effective from the current scenario, with the help of these industries having freedom to redesign and rebuild their supply chain network. Post GST, India would become a uniform, common market for Goods and services, the tax barriers and amongst the state borders eliminated. By reviewing the complete cycle of supply chain the impact of GST would lead to re-engineering of warehouse strategy by diverse manufacturers and key companies. Before GST the decisions on location of warehouses will be driven by tax considerations, interstate transactions. Warehousing decisions will from this time forth be driven by considerations like location of major customers/market and optimization of goods movement. Since any supply would be taxed, branch transfers would get discouraged leading to optimization of transport. Elimination of statutory forms (C-Form, F-Form, E1-E2 etc.) would reduce the requirement for scrutiny at state borders. After GST implementation, the design of the supply chain will be based on customer service and logistics cost. As the next level of logistics is evolving in India and the corresponding regulatory policies have to be taken care well ahead of the GST introduction to have a positive and predictable impact.

KPMG GST Report -2011

Advanced Planning Systems for Supply Chain Transformation: A Case of Indian CPG Industries

Sanjay Tripathi, Rajesh Jain

Institute of Management, Nirma University, Ahmedabad, Gujarat, India

Abstract: Companies are now seeking how to integrate decisions across supply chain functions, across geographically dispersed facilities and all time visualization of data “The fact based supply chain is crucial .the essence of fact-based supply chain management is integrated with advanced planning systems and supply chain process for better planning and control .which has three important dimension .

The first dimension is functional integration involving decisions about purchasing, manufacturing and distribution activities within the company and between the company its suppliers and customers

1. Geographical integration of these functions across physical facilities located one or several countries.
2. Integration of strategic, tactical and operational supply chain decisions.
3. Today's supply chains crave a solution that combines an accurate representation of business uncertainties, an adaptive inventory optimization, and a near-real-time status of inventories and orders.

The purpose of this paper is to propose that Supply Chain Transformation through Digitization of Demand Planning and S&OP Process for CPG Organizations, in global supply chain complexities is a result of the strategic alignment between demand planning and S&OP process to achieve supply chain strategies. The purpose of the study is to explore what potential benefits could be achieved by using APS(Advance Planning System) systems in the supply chain process, consisting of benefits divided into three types of benefits; **decision support, planning efficiency.**

The study indicated that the decision support benefit “**visualization of information**” has been underestimated in organisations by planners. The study analyses that the benefits perceived in the different S&OP activities, in the demand planning sub-process, perceived that the use of S&OP resulted in a reliable demand plan, good knowledge about the supply chain and made the planning activities more enjoyable.

The companies set up S&OP on a stock keeping unit (SKU) level, with the possibility of re-planning and a flexible planning horizon, thus differing from what has generally been suggested by various experts. In addition, the companies are aligning the inputs, activities, and outcomes of the S&OP process to the planning environment. Particularly important environmental contingencies are uncertainty connected to demand and supply, frequent new product launches, and production network complexity. Product-related variables have a higher impact on the S&OP design, planning frequency: these needs to be able to consider the demand and capacity uncertainties, as well as take into consideration supply uncertainty.

1. RESEARCH AIMS AND OBJECTIVES

The objectives of this research is to understand the real essence of supply chain integration and digitization of demand planning & S&OP process, I aim to assess the effect of demand Planning & S&OP process integration is beneficial to CPG industries supply chain performance.

51 As a result, the following research Aims and objectives have been identified

In CPG originations 90% of the cost is uncontrollable: due to hefty fluctuation in commodity and Raw Material prices with very little control, organization has to focus on 10% of operating cost which is the only controllable component within entire operation cost structure.

However small and about 10% is the key element for Market Differentiation, Thin margin business and profitability are through the volume sales in CPG industry.

Sales Growth and Increase in brands and SKU, s every month is further creating complexity in business planning which is existent due to insufficient and Manual Processes, Multi SKU, s Management across large number of locations (in production as well as Storage Space) is a big challenge.

Seasonality and Sourcing uncertainly leads to complexity in managing limited warehousing capacity and hence the difficulty in managing customer service at lowest possible supply chain costs, Customers are demanding the availability of goods in the convenient shopping and treating as commodity.

2. CPG INDUSTRY

The CPG industry typically thin margin and profitability is mainly through attaining volumes and other important characteristic is 90% of the cost is uncontrollable due to hefty fluctuation in commodity and raw material prices with very little control, organization has to focus on 10% of operating cost i.e supply chain costs, branding which is the only controllable component within entire operation cost structure.

The branding typically relates to growth plans of company have left only option to control the supply chain costs. By using the advanced supply chain planning methods these can be controllable to some extent.

The key challenge of any supply chain is make sure that right SKU should be available at right place, seasonality, sales growth and Increase in brands and SKU, s every

month is further creating complexities in supply chain. As supply chain network is large and hence manual planning and process becomes challenge. The demand fluctuations is also leads to complexity in supply chain and managing limited capacity of warehousing is also becomes difficulty which effects customer services level at lowest possible supply chain may also lead to loss of sale.

Customers are demanding the availability of goods in the convenient shopping and treating as commodity hence CPG supply chain as to deliver right SKU at right place and supply chain costs are should be with in planned costs.

3. CPG SUPPLY CHAIN

Distribution is the main driver of supply and is managed through warehouses and point of sales spread all over the country. Every warehouse handles all the SKU's to serve the market demand.

Source: Adapted from JDA network Planning -2014

4. LOGISTICS

Logistics oversees the actual transportation of the goods from one point to another. Every organization does not have own or dedicated transportation but has an empaneled or preferred Logistics Service providers with whom it has long term association. The cost depends on actual transaction and vehicles arrival at manufacturing locations.

The commodities industries like oil which imports nearly 60% of raw materials and mainly processing plants located close to port. The advantage of port based locations is that the vehicles come loaded into the port and normally do not have a return load. So the price will be lower than the dedicated vehicles. However at some ports when imports are high the situation might be reversed. But this also limits the availability because the incoming vehicles have specific

and limited destinations. The frequency of incoming vehicles for a specific destination also varies and hence vehicles may not be available on daily basis to all given location.

The vehicle availability to certain difficult destinations may not be there as per logistics requirement. The availability is also in lumps i.e. when the vehicles arrive at a port they arrive in lots.

While the problem with hinter land plants is that the in-bound and out-bound vehicles market is not mature and hence the availability is not certain and has to mostly depend on hiring vehicles from local transporters. These transporters always look for return loads and hence the availability may be delayed till return load is available. Since these hinterland plants mostly supply within the state the return load from such destinations is limited. This leads to higher cost than port based plants.

5. WHY ORGANIZATIONS ADVANCED PLANNING SYSTEMS AND PROCESS

Because of dynamic logistics contracts costs the locations of warehouses/ storage points becomes very crucial. Once warehouse locations fixed for time period then orders from markets are random hence it requires Advanced Planning tools for planning and process to execute the plan. The Advance Planning System (tools and process) for supply chain should support decision support and, planning efficiency.

6. ADVANCED PLANNING SYSTEMS

The Advanced Planning Systems (APS) will automate and enable various strategic, tactical and operational plans/decisions in the entire supply chain. The strategic, tactical and operational plans/decisions will be driven by the intelligence derived from total analysis at various stages in the supply chain – production, procurement, primary freight, storage, secondary freight and distribution. The APS will drive the intelligence with the optimization/analytical techniques and scope of applying these techniques in the supply chain is as follows:

- 1) Strategic optimization for locations and capacities of production, packaging facilities, new warehouses depots, and new markets.
- 2) Integrated tactical optimization for plant to warehouse logistics allocations including stock transfers and direct dispatches from plants to destinations (movement of finished and packed products), and procurement from suppliers to plants (movement of major raw materials and fuel).
- 3) Production scheduling for different SKU at each plant – lot sizes and sequences of different products on equipment's/production units.

- 4) Inventory stocking and replenishments at storage points – warehouse (for finished products) and plants (for major raw materials).
- 5) Transport scheduling and routing – vehicle fleet-mix at plants (for primary freight) and at warehouses (for secondary freight); daily/weekly dispatch loads and routes (for primary freight) and daily routes (for secondary distribution) including FTLs, PTLs and Milkruns.
- 6) Forecasting of demands (sales) of SKUs in markets (destinations) over short-term, medium-term and long-term – useful for the decision support models mentioned in points 1-5 above.
- 7) Real-time tracking and management of logistics and distribution from plants to markets or warehouses to markets – Reporting status of operations; Confirming tentative arrivals of goods to customers; Re-allocation, re-scheduling and re-routing in events of contingency.

The advanced planning systems will aims to cover the analysis for all the above decisions throughout the any supply chain, and their implementation, tracking and reporting. These systems will work at various levels of organizational hierarchy, at different stages in supply chain, and at different rolling time frames. However, they will work in sync with each other in an integrated manner. They will draw input data from a transactions system (I.e SAP etc) and ability to push decisions / outputs to the transaction system.

Thus, the advanced planning system will contain two components:

- A) **Decision Support System (DSS):** This will comprise all the advanced tools and models and the related data.
- B) **IT System:** This will comprise the relevant hardware, data (BI) warehouse and software interface for managing the inputs and outputs of the DSS.

The IT system will manage two major functionalities:

- i) Managing input data for DSS/ advanced models:

Input data will come from different sources ERP (SAP) system, information from GPS and RFID sensors, and custom developed interface for user-defined parameters for the models. The IT system will feed these data into the DSS/optimization models.

- ii) Managing outputs from DSS/optimization models:

The outputs of DSS/optimization models will be the recommended decisions/plans and related scenario analyses. The IT system will generate such reports and transmit them to relevant decision-making users/authorities

via dashboards. Different types of reports will be sent to different users as outlined in the next section “Description of Models”. This reporting hierarchy will be defined in the IT system.

The following figure depicts a broad architecture of advanced planning systems. The ‘Input Layer’ will gather all relevant data from various sources in supplychain and

process and push the data into the ‘DSS Layer’. The ‘DSS Layer’ will take in that data and perform relevant optimization/analytical calculations and generate results for various plans and schedules in the supply chain. These results will be pushed into the ‘Presentation Layer’ which will process them and send relevant reports to various users in organization.

Fig. 1. Advanced Planning Systems Architecture.

Advanced planning systems have the potential to create an accelerated business value but organization need understand implementation issues advanced planning systems

Fig. 2. Advanced Planning Systems for supply chain planning.

7. DESCRIPTION OF MODELS IN THE DECISION SUPPORT SYSTEM (DSS)

The following boxes provide a brief description of each optimization/analytical model in the proposed DSS of the Integrated Portal. Each box indicates the intended users of the model, objectives of optimization, time frame (rolling horizon), and key data inputs and key output reports.

Supply Chain Network Design	
Users: Top management / Heads of supply chain, logistics, production [Corporate Office]	
Objectives: Minimize all-India/regional network cost; Meet growth & service level targets	
Decision time frame: Few years, 1 year, 6 months	
Inputs •Goals of growth and expansion •Existing & candidate locations/capacities of plants, warehouses •Costs of capital, production, raw material, transport, etc.	Outputs •Optimal locations/capacities of plants, warehouses •‘What-if’ analysis for scenarios of growth, locations, tax structures •KPIs: costs, service levels, etc.

Integrated Supply Chain Operational Planning	
Users: Managers of logistics, production, procurement [Corporate Office / Plants / Regional Offices]	
Objectives: Maximize all-India/regional contribution; Minimize total cost-to-serve; Meet demands	
Decision time frame: 12 months, 1 month, 1 week	
Inputs •Existing locations/capacities of plants, warehouses, transport links •Variable costs of production, raw material, transport, taxes, etc. •Upper/lower bounds on logistics flows, market shares, etc.	Outputs •Optimal plant-warehouse-market allocations •Optimal plan of production, route-modes, procurement, inventory •KPIs: contribution margins, costs, service levels, bottlenecks, etc.

Production Scheduling	
Users: Managers of production [Plants]	
Objectives: Minimize plant level variable cost; Maximize utilization; Meet production plans	
Decision time frame: 7-14 days, 1 day, 1 shift, 1 hour	
Inputs •Weekly / monthly production plans •Production units/equipments, capacity, availability, changeovers •Costs of raw material, production, packaging, etc.	Outputs •Optimal schedules & sequence of product lots on equipments •Contingency re-scheduling – in events of break-down, rush orders •KPIs: plant level costs, utilization, etc.

Inventory Stocking & Replenishment	
Users: Managers of logistics & production [Plants & Warehouses]	
Objectives: Meet service level targets at plants and warehouses	
Decision time frame: 7-14 days, 1 day	
Inputs •Closing stocks; Weekly / monthly production and logistics plans •Service level targets for finished products and raw materials •Constraints of stock availability, funds/credit, vehicle loading, etc.	Outputs •Safety stock levels and reorder points at plants & warehouses •Orders generated from warehouses & plants •KPIs: service levels (stock-outs), deviations, inventory cost, etc.

Transport Scheduling & Routing	
Users: Managers of logistics and sales [Regional Offices; Area Offices; Sales Units; Warehouses]	
Objectives: Meet service level targets (demands); Minimize transport cost in a region	
Decision time frame: 7-14 days, 1 day	
Inputs •Weekly production and logistics plans and service level targets •Costs of primary freight, secondary freight, handling, etc. •Constraints of vehicle availability, routes/network, etc.	Outputs •Optimal vehicle/fleet-mix at plants and warehouses •Primary freight schedules; Secondary routes – FTL/Milkrun/PTL •KPIs: on-time deliveries, vehicle utilization, transport cost, etc.

Demand (Sales) Forecasting	
Users: Managers of sales & logistics [Sales Units & Warehouses]	
Objectives: Forecast sales (demand) and meet sales targets	
Decision time frame: short-term (1-7 days), med-term (1-12 months), long-term (1-2 years)	
Inputs •Daily sales in the past 3 months (SKU-Destination wise) •Last two years' monthly sales to capture seasonality •Other causal factors and expert/user inputs of trends & targets	Outputs •Short-term sales forecasts (next 1-7 days) •Med-term sales forecasts (next 1-12 months) •Long-term industry/market and sales forecasts (1-2 years)

Real-time Operations Tracking & Scheduling	
Users: Managers of logistics, plants and sales [Plants; Regional Offices; Sales Units; Warehouses]	
Objectives: Respond to real-time contingencies; Meet service level & other priorities; Minimize cost	
Decision time frame: Real-time (1 day, 1 hour)	
Inputs •Day's production and logistics status: work-in-process & schedules in plants, primary freight, secondary freight (distribution) •Contingency events: e.g. stock-outs, rush demands, break-downs, etc. •Constraints of vehicle availability, on-going schedules, resources, etc.	Outputs •Re-allocations and re-schedules in response to contingencies: in plants, primary freight, secondary freight (distribution) •Reports of current status of production and logistics •KPIs: on-time deliveries, delays, costs, etc.

8. PROCESS

The DSS will work at different hierarchy level and different time horizons and order execution is at lowest level hence planning process need to design for seamless integration of DSS decisions. These process also support organisation to setup a cross-functional decision process which reconciles conflicting business plans, links strategic planning and operational planning, and aligns company resources to deliver one enterprise plans.

The key process demand planning process, supply side planning process, stock replenishment process, order execution process etc. The most important aspect of advanced planning system the decisions should seem lessly flow from one department to other department and facilitate the collaborative planning of production, sales and logistics departments.

For many enterprises today challenges are increasing:

- Managing a more complex supply chain – maintaining visibility and control.
- Achieving greater responsiveness and agility – respond quickly to changing market conditions & new business opportunities seamlessly.
- Enabling growth and delivering value – beyond cost control, delivering business value and driving profitability.
- Service Improvement & Higher Delivery Expectations – enhanced quality of service to end users.-

- Risk Reduction – business continuity & security of supply Companies which are able to master these challenges effectively are more equipped to get ahead of competition and quickly adapt to new market realities by delivering new models of Supply Chain operation, achieving true flexibility and responsiveness, and more strategically targeted performance improvement

The Sales & Operations Planning (S&OP) and demand planning are emerging best process in FMCG industry and same process can also be implemented in CPG industry.

S&OP Process

Sales & Operations Planning (S&OP) is a set of decision-making processes to:

- Balance demand and supply
- Integrate financial planning and operational planning
- Link high-level strategic plans with day-to-day operations.

9. DEMAND PLANNING

The demand planning process streamlines the efforts of the sales, marketing, finance and operations departments to match demand and supply contributes to the appropriate use of resources in the fulfillment of customer demand.

Demand planning and forecasts enable the manufacturing department to plan production to meet customer requirements. The forecasts also support the purchasing

department's efforts to correlate deliveries of materials and supplies with production schedules. In turn, a forecast also alerts finance to the level of investment in plant, equipment and inventory required to meet demand as well as the budgets to be created to manage the business. The demand

forecasts also affect the personnel department's hiring and training decisions and the marketing department's assignment of resources to particular product groups or marketing campaigns.

Supply Chain –Synchronization Model

10. WHY ORGANIZATIONS NEED DEMAND PLANNING AND S&OP PROCESS

Source: Adapted from Gartner Magic quadrant on demand Planning -2014

Globalization in the digital world means that the supply chain — efficiently moving products and services from one place to another — needs to be a core competency of every organization. Companies need to think about how they can create greater efficiencies in their global supply chains, while remaining nimble enough to respond to new opportunities in emerging markets and meet customers' complex demands. Technology can help streamline costs, but it can also be a vehicle for opening up new growth avenues, managing supplier risk, and efficiently sourcing materials from partners located around the world. Mobility and social media platforms are also influencing customers' expectations and putting power in their hands. As a result, businesses are feeling heightened pressure to deliver products and services in a timely, customizable way. This shift is influencing how companies interact with partners and suppliers.

(Source adopted from -Chain-link Research - 2015)

These trends are just as much opportunities for transformation as they are challenges, but companies need to think about their response strategically. They must adapt their structures to be more flexible and responsive, balancing cost controls with the need to maintain an integrated view of the supply chain across businesses and geographies. Given the complexities of global supply chains, organizations should take an incremental approach, first tackling a key process, division, or business unit that has the best likelihood of delivering the greatest value. For some companies, this might mean re-evaluating their sales and operations (S&OP) planning processes, leveraging in-memory solutions such as SAP HANA to make S&OP more of a strategic cross-functional discipline that is better aligned with business goals. Organizations should also consider how they can take advantage of cloud solutions like the cloud version of SAP Sales and Operations Planning to enhance their ability to collaborate internally and externally with partners and customers to create efficiencies, facilitate better customer service, and increase sales while controlling costs. Piloting such a solution may be the quickest way to get started on the path to technology enablement of these objectives.

Companies need to create greater efficiencies in their global supply chains, while remaining nimble enough to respond to new opportunities and meet customer demands.

The goal of many companies is integrated business planning. While integrated business planning lacks a common definition in the market, the most successful companies focus on the integration of process versus the integration of numbers. For example, in a mature company, the focus is agreement on a common plan, not a one-number forecast. There is a focus on the consideration of inputs into budget refinement, but the S&OP plan is seldom

constrained by the budget. Tight integration of the financial budget to the S&OP planning process is a recipe for disaster.

Leaders in this industry use sales and operations planning to determine effective promotion strategies, sense consumption through store clusters and point-of-sale (POS) data from vendor-managed inventory (VMI), and time new product launch activities by account. They identify S&OP as a key process to improve time to market for new product launch activities and as a means to align cross-functional teams on market opportunities. While CP companies were early leaders in the use of supply chain planning technologies, they lag other industries on the development of demand-driven S&OP processes. The primary demand-shaping mechanism is trade promotion activities.

11. CONCLUSION

APS are identified as potential support tools for managing complex SCM problems and as means for supply chain integration. This paper fills some of the knowledge gaps about how this could be done and the perceived effects of using APS, focusing on the strategic and tactical planning levels. Three explorative case studies show how APS can enhance SCM in various situations. Noteworthy is that all three cases are centred on the software use of a so-called SCP module, but the module is used on different planning levels addressing different problems.

Despite great progress in modelling and solution capabilities there are still many areas for improvements and for future research in SCM and AP. While the issues facing an inter-organizational SC are mainly addressed in research areas associated with the integration of individual organizations, our knowledge regarding process orientation and advanced planning across company borders is still in its infancy (Croom et al., 2000). As we have pointed out not only the underlying mathematics is concerned but also interdisciplinary research incorporating computer science, accounting and organizational theory,

In an effort to improve organisation competitive position in a rapidly changing marketplace, many companies have replaced their traditional supply chains with extended and advance supply chain networks built on a foundation of supply chain collaboration. These extended networks require the use of decision support tools and technologies to improve both operating efficiencies and customer service, but many companies have struggled to realize the expected benefits of these tools and the increased collaboration. This article recommends that companies adopt an integrated strategy of people, processes, and technology to achieve their competitive supply chain goals. Our recommendation is backed by the results of a survey we conducted of senior level practitioners concerning the importance and challenges of supply chain collaboration. The article

concludes with a set of managerial recommendations to improve a company's collaborative efforts within its supply chain.

The relationships between APS, planning organization and planning effects are thus obvious in these cases. Several positive effects of using APS as support for global SCP on strategic and tactical levels were identified, but the research conducted here also identifies and motivates several future research areas about the appropriateness and performance of APS usage.

Reverse Logistics Facilities Network Configuration for Rubber and PET Products: An Industrial Case Study

Uday K. Chhaya

Department of Industrial Engineering
Shantilal Shah Government Engineering College, Bhavnagar, Gujarat, India

Abstract: In the present work, key reverse supply chain constituents contributing to sector-specific network have been examined through industrial survey for both types of product returns: end-of-life; and end-of-economic use. Further, the determination of the number and location of different facilities like collection centers, re-manufacturing centers, disassembly centers, recycling centers, disposal centers is demonstrated through real-field data of returns-flow and transportation costs of the products, and also for the intra-stage quantity-flow between facilities in the reverse supply chain.

An industrial survey of the rubber and PET (Polyethylene Terephthalate) product industries in and around NCR and the state of UP for configuration of physical reverse logistics networks has been shown. Further, use of optimized mixed-integer linear programming model to derive solution by Lingo solver is presented to determine numbers and locations of different key constituting facilities for the reverse logistics network, with an objective of minimizing the supply chain cost.

Keywords: Reverse Logistics, MILP

1. INTRODUCTION AND LITERATURE REVIEW

Fast growing economies like India observe a large and growing market for economic extension of product life through reuse and thereafter, a safe disposal. According to the Environmental Protection Agency, there are 20-50 million metric tons of waste electrical and electronic products generated worldwide every year, comprising more than 5 per cent of all municipal solid waste (L. L. D. C. S.-Y. and Y. V. Dat, 2012).

The economics and control over product return is far more complicated than that of the forward flow, for, reverse supply chain is generally not as much profitable as that of a forward supply chain. Contributing factors to this could be skewed ratio of capacity utilization of transport facility to the frequency of availability requirement of the product. Another aspect could be uncertainty over the quality variations of the returned products. Due to this, all the products collected cannot be remanufactured or sometimes, more advanced operations are required for making the returned product resalable (R. S. Sajan T John, 2015). This will necessitate bringing the total cost down so as not to let it consume profit margin.

Available research and literature describe about well-managing reverse logistics network to provide cost savings in procurement, recovery, disposal, inventory holding and transportation over and above helping in customer retention. Proper modelling could help reduce total reverse supply chain cost (V. J. and V. W. L. Guide). An increased thrust on environmental implications is also well documented (S. R. F. and K. H. Kara, 2007). Companies,

like Kodak, Xerox and HP which focus on remanufacturing and recovery activities, thereby achieving significant gains (H. E. G. A. E. and Ç. S. Üster, 2007).

The returned products can be classified into a number of categories. In this paper, we consider two types of product returns: One that have come to end of economic use (which can be refurbished and can be resold into secondary market); and the other, that have reached end of life (to be safely disposed-off). A framework based on the economic value analysis concept has been suggested (V. J. and V. W. L. Guide, 2001).

A mathematical programming model with heuristic solution methodology for problem solving was proposed (V. P. R. and R. E. Jayaraman, 2003). A genetic algorithm to design a reverse logistics network involving products returned was proposed by (H. K. H. and K. C. Min, 2006; and Y. a. W. S. Zhou, 2008). Zhou et al proposed a reverse distribution network design with the repairing and remanufacturing options.

Mixed-integer programming has been the most adopted modelling technique by many researchers focusing on varied components of supply chain like location-allocation of repair facilities with a TPL provider. Also, an integrated, multi echelon, multi period, multi-product mixed-integer linear programming model is suggested to optimize the distribution and inventory level for a closed loop supply chain network. These contributions take examples from different sectors like lead acid batteries, tumble driers, end-of-life vehicles, etc.

The review of the literature shows that, even though, there are lots of works in the area of reverse supply chain, only a few researchers have addressed the issue of development of a general framework for the network design. Most of the works in this area are limited to either a single type of product return (e.g. end-of-life) or a single type of recovery option (e.g. remanufacturing) (R. S. Sajan T John).

2. METHODOLOGY

In the present work, key reverse supply chain constituents contributing to sector-specific network have been examined through industrial survey for both types of product returns: end-of-life; and end-of-economic use. Further, the determination of the number and location of different facilities like collection centers, remanufacturing centers, disassembly centers, recycling centers, disposal centers is demonstrated, through real-field data of returns-flow and transportation costs of the products, components and materials between each stage in the network and also for the intra-stage quantity-flow between facilities in the reverse supply chain.

3. REVERSE LOGISTICS CONSTITUENTS

In reverse logistics, it has been established that there are three fundamental stages of flow (M. P. D. and R. Dekker, 2003; Fleischmann et al, 2004; T. U. A. a. B. A. Daim, 2013):

1) Collection, 2) sort-test, where decisions like whether to recycle/dispose-off, or remanufacture for secondary market are taken, and 3) processing (Done at recycling or remanufacturing centers)

As T. U. A. a. B. A. Daim, 2013 observes, companies need to choose how to collect recoverable products from their former users, where to inspect collected products in order to separate recoverable resources from worthless scrap, where to re-process collected products to remarket them, and further, how to distribute recovered/remanufactured products to primary/secondary customers.

For our case, the determination of the number and location of different facilities like collection centers, remanufacturing centers, disassembly centers, recycling centers, disposal centers for the reverse logistics of rubber, tyre and PET industries is demonstrated, along with the quantity of flow of products, components and materials between each stage to be established in the network and the quantity of flow of products, components and materials between each stage of the supply chain.

A reverse supply chain, existing in NCR and UP industrial zones, consisting of five market clusters, five locations for collection centers, three locations for remanufacturing centers, four locations for disassembly centers, three potential locations for recycling centers, one disposal center, two secondary markets and two primary markets are considered.

The problem involves the determination of the number and location of different facilities to be established in the network and the quantity of flow of products, components and materials between each stage of the supply chain. The objective minimizes the total cost comprising of transportation cost, processing cost, fixed facility cost and disposal cost. The network is modelled (adapted from R. S. Sajan T John, 2015) and optimized using mixed-integer linear programming formulation with minor customizations, that minimizes the total cost of the multi- stage reverse supply chain and further solved using solver Lingo.

Fig. 1. Reverse logistics constituents

4. INDUSTRIAL CASE AND INPUT DATA

A real reverse supply chain consisting of five market clusters, five potential locations for collection centers, three potential locations for remanufacturing centers, four potential locations for disassembly centers, three potential locations for recycling centers, one disposal center, two secondary markets and two primary markets are considered. The coordinates of the different facilities are generated by Google maps (not shown, used only for generating distance-matrix).

In Exhibits 1 through 8, flow, cost and distance data between existing facilities is shown. The quantity of used products available for collection at market clusters are shown in Exhibit I. Exhibit II shows the distance matrix between market clusters and collection centers.

Exhibit III shows the distance matrix of collection centers with disassembly centers and remanufacturing centers. Exhibit IV shows the distance matrix between remanufacturing centers and secondary markets.

Exhibit V shows the distance matrix of disassembly centers with recycling centers and disposal center. Exhibit VI

shows distance (in KM) between recycling centers and primary markets.

5. RESULTS AND DISCUSSION

The problem is solved and optimized for a realistic situation on the pre-modelled MILP formulation. Solution tables 1 through 6 (R-1 through R-6) show the values of optimized flow and derived decision support for locational decisions for facilities to carry out constituent activities. Also shown in R-1 is the optimized cost figures.

The application of the model to the real industrial scenario provides optimum decisions for the said industrial clusters, and can be applied to cluster of similar industries. Also, through some customizations, it can further be extended for other industrial domains engaged in reverse logistics activities.

6. FUTURE WORK

The proposed model is a general one and with the proper analysis of the results obtained, it helps to analyze the long-term operation of a reverse supply chain. Further, only a single product-variants, single-period situation has been considered, and it could be further extended by considering a multi-product, multi-period situation. The uncertainty in data can also be incorporated into the study as a future research.

Remanufacturing Scheme Based on RUL Assessment

Umangi D. Pathak, Ravi Kant

Department of Mechanical Engineering
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

Abstract: To estimate the Remaining useful life (RUL) left on a component at a particular time of operation is a vital area of research. RUL is established on maintenance and prognostics and health controlling fundamentals. RUL is typically arbitrary and indefinite as it involves various uncertainties with its calculation. The research focuses various models to estimate RUL from available sources of information using various tools and techniques which helps decision makers to find optimum policy for reuse, remanufacture and recycle.

Keywords: Prognostics, Remaining Useful Life and Remanufacturing schemes

1. INTRODUCTION

Prognostics is a skill of predicting future behavior component and identifying possible failure models resulting in computation of the remaining useful life of the component or system. It's defined as a prediction of once the failure may occur and methodology calculates the remaining useful life on an asset. (Smith. A. E. et al 2003) defined prognostics as the ability for early detection and separation of pioneer and/or initial fault condition of a factor or element. A prognostic builds on the diagnostic as a section and are defined as the capacity to predict the progression of fault condition of component failure and estimate the remaining useful life (RUL).

The remaining useful life (RUL) of component is defined whereas the length from the current time and to the end of the products useful life. RUL is applicable in theoretical and real life. Remaining useful life modeling and its assessment provide us the timely information for system for decision making, production management and condition based maintenance (Bagul Y.G. 2009). RUL is a device with vital usefulness in remanufacturing (Chen C., et al 2010), to take full benefit of the life of a device before remanufacturing, the RUL measurement is one of the best plan before any decision.

RUL prognosis is one of the key factors in condition based maintenance (CBM), and prognostics and health management. RUL prognosis techniques are tremendously desired for health management of degrading systems in order to avoid and prevent sudden breakdown and decrease the rate of hazards. RUL guess techniques can be wanted for wellbeing administration of debasing frameworks in order to avoid sudden disappointment and decrease the danger (Yang J., Jay L. 2007). RUL estimation, offers direction for successive management and investigation of inspection schedule, maintenance and replacement activities.

2. RUL EVALUATION APPROACHES

RUL estimation carries various methods to find optimum service life of component. (Bagul Y.G, et al, 2008) listed various methods to find RUL of a product is shown in fig.1. followed with the comparison table in Table 1.

2.1 Physics based methodology

Physics based methodologies are significant in circumstances where exact theoretical models may be built. These models must certainly be designed particularly for the systems may be checked and able to precisely simulate the responses and command signals. This method is helpful in various working conditions also. Having an intelligent monitoring system, they function excellently under any load conditions of undetermined, temporary and unexpected conditions of operations. These models normally include technical information thorough hypothetical models to represent the physics of the component. For hazard and proportional risk rate (Wang W., Zhang W. 2008) proposed a stochastic procedure, called gamma process, with risk rate (HR) while the mean for the expectation of remaining life. Nonlinear flow demonstrates approach anticipated the remaining life of a musical instrument with a nonlinear procedure.

2.2 Data driven methodology

Data driven strategies, does not required any comprehensive data of the component. They are based on condition and observing/ monitoring data. Methodology became helpful when noisy data required to be changed into logical data to evaluate the RUL, (Yang J., Jay L. 2007).

RUL estimation is dependent upon extent quantity and qualities of the data. Data driven methodology are developed by collecting input and output data by various methods. Data driven prognostic technique is dependent upon statistical systems while most that begin in the

Fig. 1. Approaches for the RUL evaluation

theoretical data. Such approaches envelop traditional numerical calculations, like linear regression, algorithms, data mining, neural networks, decision trees etc.(Peng et al 2010).

2.3 Experimental based methodology

Experiments are defined as the best method to enhance the knowledge of component's life has been a vital approach in research and industry since automation is found its way to manufacturing practices. (Keller et al. 1982 and Groeret al. 2000).

Theoretical modeling became second selection of researchers because experimental research in industry is a must but while the behavior of machines is understood by analyzing the experiments it becomes most prominent step among all. Thus, experiments are often are the first and most important step for a researcher. (Chen et al. 2010) used experimental data from the key gearbox of a UH-60 helicopter, as this method is also used to validate other methods.

2.4 Hybrid methodology

In prognostic processes, parameters are miscellaneous it difficult to be predicted with by only one estimation method and results obtained with a single method isn't completely reliable. Now researchers adopting to make use of multiple method in conjunction produce for more accurate results

(Bagul et al. 2009) resulting methodology is termed a cross methodology.

TABLE 1.Comparison of Prediction Methodology

Physics based Models	Data driven Models	Experimental Models
It is highly accurate model if physics of the system remains reliable across the system.	Models transform high-dimensional noisydata in to prognosticdecisions and also measures input/output.	Manipulations in data set can be controlled. Possibilities to add trend analysis based on theexperimental data.
Model is based on various assumptions and empirical considerationsof physics parameters.	Model does not require assumptions or empirical estimations of physics parameters.	Models are almost always needed to verify other theoretical models.
Computation of this model is expensive.	Easily to calculated and envisage further states. But prediction horizon is shorter.	Experimental models are often costly.
It can be built with less input dataset compared to data driven method.	Gives poor result with high dimensional data. Accuracy of data set increases accuracy of measurement	Theoretical and experimental models generates more accurate output.

3. UNCERTAINTY IN RUL MEASUREMENT

There are some sourced elements of uncertainty which affect the estimation of future behavior and consequently the rest of the useful life prediction. Those sourced elements of uncertainty, is practically impossible to exactly so estimate hence the rest of the useful life prediction becomes more uncertain. It may even more challenge to identify and quantify the different sources of uncertainty that affect prognostics. Such categorized the different sources of uncertainty into different sets in order facilitate uncertainty quantification and management. Prognostics

based decision-making model it is important to analyze how the many sourced elements of uncertainty affect the rest of the useful life prediction, in order to accurately estimate the uncertainty in the RUL prediction and inform the decision maker regarding such uncertainty (Bagul Y.G. 2009). Tasks need to be performed for accurate estimation of the uncertainty in the RUL prediction and update the decision maker regarding such uncertainty. Modeling errors, , sensor noise and, state, future loading, model parameters, operating and environmental conditions, measurement error etc. are common source of uncertainty (Keller A., Perera U., Kamath A. 1982).

TABLE 2: Stages to Reduce Uncertainty

Uncertainty Illustration and Interpretation (Bukapatnam S.T.S 1997)	In this stage level of uncertainty is measured lots of practical applications are guided by the possibility of modeling and simulation frameworks from pair of theories like: classical set theory, fuzzy set theory, fuzzy measure theory, probability theory rough set theory, etc. The strategy for uncertainty representation that vary in the level of datasets and detailing.
Uncertainty Quantification	The following stage is to handles identifying and characterizing the sources of uncertainty that may affect prognostics and RUL estimation. Aim of this is to manage all these uncertainties individually and enumerate those using probabilistic or statistical methods.
Uncertainty Propagation	This stage is highly relevant to prognostics, because most of the previously quantified uncertainties and uses these details to predict the near future states and the associated uncertainty; and for remaining useful life and the associated uncertainty
Uncertainty Management	Uncertainty administration is in reference different activities which assist in managing uncertainty in condition-based maintenance during real-time operation.

4. DECISION CRITERIA BASED ON RUL RESULTS

Remanufacturing of a part can be a choice as a most valuable task as using the components whole life base on reliability. Deciding the very best time to pull the part from service for remanufacturing as a function of total cost optimization and reliability function various calculations are required. (Usynin A.V, 2007), decision for remanufacture, re-use and recycle is proposed based on data, forecasts, information of the performance and reliability value.

Decision criteria is founded on, reliability of component at time as $R(t)$, measuring/ predicting reliability of the exact same component $R(t+l.\Delta t)$ at time $t+l.\Delta t$. Predefined threshold reliability R^* is defined for every product. Measuring current reliability $R(t)$ and reliability after time is $R(t+l.\Delta t)$ we can take decision for remanufacturing.

You can find three different solutions for the remanufacturing scheme (Xugang et al 2007), as shown in the next:

1. Reuse: Reuse the product without remanufacturing if the present time reliability $R(t)$ is larger than the predefined threshold reliability R^* , and the near future reliability at $t+l.\Delta t$ time is $R(t+l.\Delta t)$ is also greater compared to the threshold reliability R^* , as in Fig.2(a). $R(t) > R^*$ and $R(t+l.\Delta t) > R^*$.

2. Remanufacturing: Product could be used effectively up to the worth of reliability is higher than threshold reliability. Product could be remanufacture if present time reliability $R(t)$ is superior to the predefined threshold reliability R^* , and the prospect reliability at $t+l.\Delta t$ time is $R(t+l.\Delta t)$ is less than the threshold reliability R^* , as in Fig. 2(b). $R(t) > R^*$ and $R(t+l.\Delta t) < R^*$.

3. Recycle: The possibility of the products failure is relatively frequent and to improve operational reliability of the merchandise, remanufacturing is preferred, but after that recycle phase come in to account. Product can be recycle if the present time reliability $R(t)$ is fewer than the predefined threshold reliability R^* , and the future reliability during the time $t+l.\Delta t$ is $R(t+l.\Delta t)$ is also less compared to the predefined threshold reliability R^* , as in Fig.2(c). $R(t) < R^*$ and $R(t+l.\Delta t) < R^*$. Reliability of product is decreased below the threshold margin and struggling to perform the specified operations, so it's advisable to recycles.

Fig.2(A) Reuse as an conclusion

Fig.2(B) Remanufacturing as an conclusion

Fig.2(c) Recycle as an conclusion

5. CONCLUSION

Accuracy in prediction of maintenance strategy has received a lot of attention as engineering focus on reducing high maintenance costs, timely delivery and operation downtime and safety working environment became prime for any organization. Maintenance and prognostics is essential; as they estimates and improves the RUL of equipment which prevents inopportune maintenance expenses. RUL can be measure using various methods explain in the paper. Based on reliability value decision maker can make decision for remanufacturing. This data-driven method is followed by steps of data gathering, training, and exercise for the model construction is necessary. The theory connects the remanufacturing scheme with the performance reliability and RUL serves as best tool for remanufacturing decision. The prediction of remaining useful life in engineering systems is afflicted with several sourced aspects of uncertainty, and it is important to suitably interpret this uncertainty to be able to assist significant decision.

Supply Chain Performance Measurement: A Literature Review

Maresh L. Deshpande, Pratik A. Patil

*Department of Mechanical Engineering
Rajarambapu Institute of Technology, Sakharale, Maharashtra, India*

Abstract: *In today's competitive business environment, supply chain performance is one of the most critical issues in various industries. It is stated that supply chain performance measurement is fundamental to efficient supply chain management. Over the past two decades, several frameworks and systems have been developed to meet this need. This study reviews the literature in the field of supply chain performance measurement and gathers an overview of those systems, approaches, techniques and criteria. Findings disclose that performance measurement in supply chain contexts is still a fruitful area of research. The study also provides an overview of the performance measures employed in supply chain systems.*

Keywords: *Supply Chain, Sustainable supply chain, Critical success factors*

1. INTRODUCTION

A supply chain (SC) is a set of processes that are linked together the activities such as the procurement, logistics, production and distribution of products to customers (Zanjirani, Farahani, and Davarzani 2009). Supply chain management (SCM) has strategic relevance because increased competitive pressures have pushed many firms to turn their supply chain into competitive weapons to enhance performance (Fine, 1998). Critical success factors (CSFs) of SCM represent a wide variety of strategies devoted to improving operational efficiency and competitiveness of SME. To effectively compete in the global market, SMEs must have effective SCM performance measurement system.

In view of this, objectives of this paper is to study the literature related to supply chain performance measurement. We will discuss the background for the research, review the selected literature on supply chain performance measurements, and finally, summarize the findings and conclusions.

The rest of this paper is organized as follows. Section 2 briefly reviews the literature on supply chain performance measurement. Finally, conclusions are presented in Section 3.

2. LITERATURE REVIEW OF SUPPLY CHAIN PERFORMANCE MEASUREMENT

In this section, the literature is used in relating the general perspective within which measurement of supply chain performance is undertaken. The works of various authors are used in establishing the need for supply chain performance measurement are considered in this paper.

Luque et al. (2015) focuses on the interrelationships among the different dimensions of supply chain integration. Specifically, it examines the relationship between employee commitment and supply chain integration dimensions to explain several performance measures, such as flexibility, delivery, quality, inventory and customer satisfaction. The findings suggest that the relationship between employee commitment and operational performance is fully mediated by supply chain integration. Employee commitment contributes to improving internal integration, and internal integration affects performance both directly and indirectly. Moreover, obtaining internal integration helps to achieve supplier and customer integration. Author gives various dimensions of supply chain performance measurements. Author also claimed that lack of qualitative research in this area (Luque et al., 2015).

Top management commitment, long term vision, focus on core strengths, devoted resources for supply chain, and development of effective SCM strategy emerged as the most pertinent CSFs. To measure improvement in performance, different measures related to customer service and satisfaction, innovation and growth, financial performance, and internal business should be included (Kumar, 2015). It is possible to improve supply chain performance by implementing Lean SCM practices. That is particularly important in a country that has high interest rates and needs to compete in a global market (Tortorella et al., 2017).

Payman et al. (2016) proposed an integrative multidimensional framework for a comprehensive evaluation of SSC performance. The key contribution of research presented in this literature is that the proposed stochastic framework is capable of accommodating any number of performance characteristics associated with

SSCM. The framework is not restricted to the three traditional areas of the triple bottom line, namely economic, environmental, and social issues. This is important given the wide range of challenges and opportunities present in different supply chains. It is recognized that a key challenge in applying the framework is data availability and quality. The proposed framework provides a genuine foundation for evaluating the performance of SSC while the cumulative impact of all the involved factors in all the entailed periods is taken into account. Lastly, by considering as many SSCM characteristics as may be involved, the proposed framework can be employed as a practical tool by decision-makers who aim to effectively highlight and/or manage the required reference points, when identifying the available opportunities and challenges for improving their SSC performances. The developed framework may also provide opportunities for making performance comparisons between various SSCs, provided that the entailed required data are collected, allocated, and reported in the same way across all the SSCs under comparison.

There are number of factors which urge company executives to seek new types of metrics to evaluate the performance of supply chains (Lambert and Pohlen, 2001):

- need to go beyond the limits of the company's business,
- lack of metrics covering the entire system of cooperating links,
- need to determine the range of cooperation between cooperators,
- complexity of processes,
- need for information exchange in order to achieve objectives,
- need to broaden the perception of supply chains,
- distribution of costs and benefits among the partners,
- need to diversify supply chains,
- encouragement to develop cooperation in order to improve processes.

Other authors also notice this problem and stress that there are no methods for measuring the performance of supply chains as a whole, the metrics and indicators applied do not reflect the complexity of processes and the applicable criteria are not closely linked to the supply chain strategy (Lapide, 2010). Despite efforts to integrate a supply chain, the measurement aspect gets out of this coordination. Supply chain measurement is not a single coherent system, but actually a model of measuring the performance of individual companies as if they worked independently. Each link in a supply chain has its own system. What is worse, often the same aspect of measurement is interpreted differently by individual companies. Therefore, it is

absolutely necessary to use the same terminology and apply common metrics, which are understandable for all cooperating links and which really measure the performance of the entire system adequately.

Yinan et al. (2017), developed a comprehensive model that facilitates an understanding of relationships among operations strategies, supply chain strategies, supply chain integration, and firm performance. It is a start to understand the role of operations strategies in supply chain design. Structural equation modelling is adopted to test the relationships based on data collected from 604 Chinese manufacturers. The results showed that a lean supply chain is appropriate for firms placing higher priorities on cost, quality and delivery strategies, while an agile supply chain is appropriate for firms competing on the flexibility strategy. Furthermore, both lean and agile SCSs require higher levels of SCI in terms of internal and external integration, but lean SCSs have a significantly higher impact on external integration than agile SCSs. The study refreshes the links between order winner/qualifier and supply chain strategies. Clear-cut differences exist concerning the role of operations strategy in supply chain management, indicating that appropriate supply chain design is very important for firms to achieve their operations objectives. This study contributes to a better understanding of the match between operations strategies and supply chain strategies, and offer a practical insights on investments in the development of supply chain integration.

M. Agung Wibowo et al (2015), developed SCOR model to measure performance of supply chain at road construction project. Research in industry and organization, about performance measurement of supply chain explains the Supply Chain Operations References (SCOR) with dimensions of reliability, responsiveness, flexibility, costs, and assets (D. Irfan, 2008). The previous study about the measuring performance of supply chain in house building indicates that the framework is needed to identify the balance of supply chain performance. Supply chain performance measurement on the road project has not been much discussed today. As it is known that the road project is one of very high construction project roles. The road becomes a liaison between local lands. In addition, road project becomes the backbone of the economy of a region wheel movements with the mobilization of people and goods from one area to another. Road project requires a strong supply chain, especially road with high function such as toll roads. Therefore, supply chain performance measurement on road projects is necessary to determine the ability of contractor. Performance measurement using the Supply Chain Operations References (SCOR) will analyze how the supply chain management of contractor is. SCOR will analyze how the reliability, responsiveness, flexibility, cost, and assets of the contractor. Based on the analysis, it can be seen how the performance and readiness of the

contractor in supply chain management. The more ready supply chain of contractors in road project, the higher the possibility of subject to success.

Madjid Tavana et al. (2016) proposed model that can be used both under the constant returns to scale and the variable returns to scale assumptions and can be easily implemented for comprehensive analysis of multi-level supply chains. We present a numerical example to demonstrate applicability of the proposed model and exhibit the efficacy and effectiveness of the proposed algorithms and procedures. In particular, the numerical results demonstrate that the entire supply chain is “comprehensively” efficient only if efficient supplier–manufacturer and manufacturer–distributor relationships are established.

Dominique Estampe et al. (2013) prepared framework which analyzes various models used to assess supply chains by highlighting their specific characteristics and applicability in different contexts. It also offers an analytical grid breaking these models down into seven layers. This grid will help managers evolve towards a model that is more suitable for their needs.

3. CONCLUSION

Thus in this article fundamentals regarding the supply chain management are discussed in the introduction session. Also, importance of performance measurement of supply chain management are elaborated. Section 2 describes about the quantitative literature available on performance measurement of the supply chain. In this number of authors have proposed frameworks or quantitative models for evaluating or measuring the performance of supply chain. Also some cases like road construction business and its performance evaluation are explained.

Thus after reviewing the literature it is concluded that performance measurement of supply chain is more fruitful area of research and lot of work can be carried out on the prescribed area.

Cloud Computing: Supply Chain as a Service

Nayantara¹, Rohit Kumar Parhi², Vaishnavi R.³, Ramaa A.⁴

^{1,2,3,4}Department of Industrial Engineering and Management,
R.V. College of Engineering, Bengaluru, Karnataka, India.

Abstract: The severe competition prevailing in today's marketplace makes it integral for firms to maximize their operational efficiency and responsiveness. Optimization of the supply chain can aid organizations in attaining the dynamism to achieve the same. Cloud computing is an emerging technology which has the potential to enable this optimization through flexible outsourcing software that provide platform, software and infrastructure services for the whole supply chain network via Internet. Despite the myriad benefits, the limitations and risks while incorporating the same must be taken into account. This paper focuses on the application of cloud computing in improving the supply chain collaboration and visibility needs. The pros and cons of adopting this technology in dynamic supply chains is further discussed.

Keywords: Cloud Computing, Supply Chain Management, SaaS, PaaS, IaaS

1. INTRODUCTION

The supply chains of today are highly fragmented and dynamic with silos of information that make it almost impossible to share information with all the trading partners. Therefore, to have a competitive edge in the market, businesses must be able to make quick decisions to re-route shipments, track products, communicate and collaborate with the entire global trade network to meet customer demand.

Cloud computing is one such service which makes it easy to share massive amounts of information across a complex supply chain. It is a technology that helps in the delivery of on-demand computing applications and services over the internet on a pay-for-use basis. Cloud computing consists of three different service models namely Infrastructure-as-a-Service (IaaS), Platform-as-a-Service (PaaS) and Software-as-a-Service (SaaS), each one of them serving different requirements of cloud users.

Infrastructure-as-a-Service (IaaS): IaaS model is a platform through which businesses can avail equipment in the form of hardware, servers and storage space on a pay-as-you-go basis.

Platform-as-a-Service (PaaS): In this model, cloud providers host a computing environment including an operating system, data base and programming language execution environment, where users develop or deploy applications.

Software-as-a-Service (SaaS): SaaS model is a software delivery model providing on-demand access to applications through a web browser or a program interface.

The application of cloud computing concept in the context of supply chain management is an innovative practice that

generates a new field of study with numerous advantages such as capital investment savings, simplified operations, flexibility, real-time visibility, as well as sustainability in the supply chain. These advantages offered by cloud computing help organizations to maintain alignment between ever-evolving supply chain initiatives and IT, thus enhancing firm agility which refers to an organization's ability to sense, adapt, respond and perform well in the face of rapidly changing environments. However, risks and limitations such as security of private information should be taken into consideration before applying cloud computing in modern supply chain networks [Graham et al., 2013].

The following sections of the paper are structured as follows. Section 2 briefly reviews the literature on adoption of cloud computing in supply chain management. Section 3 explains the concept of supply chain as a service. The entire supply chain management of an organization is divided into four cycles and the benefit of using cloud technology in each of these respective four cycles is mentioned. To give a more holistic view, the positive and negative impact of using cloud computing in global supply chains is mentioned. Finally, the conclusion is presented in section 6.

2. LITERATURE REVIEW

Digital Supply Chain integration is becoming increasingly dynamic. Access to customer demand needs to be shared effectively, and product and service deliveries must be tracked to provide visibility in the supply chain. Business process integration is based on standards and reference architectures, which should offer end-to-end integration of product data. Cloud integration can be expected to offer a cost effective business model for interoperable digital supply chains [Korpela et al., 2017]

This 2016 supply chain trend will continue as best-in-class organizations leverage business networks to create a digital community of partners executing coordinated processes in a more organized and informed and create value for all parties involved in it[Kayikci, 2018]

Cloud storage has revolutionized many industries and logistics is no different. By implementing self-updating and hosted computer systems, cloud storage offers many benefits to warehousing include cutting down on maintenance, infrastructure and labour costs that come from the installation and upgrading of warehouse management systems. Another benefit is that cloud storage systems are often self-updating. This means that, instead of replacing talented tech-savvy members of the team once they leave, a system can be implemented that is cost effective and easy to use by all members of staff [Tirkkonen, 2017]

New cloud computing technologies are enabling breakthrough innovations in supply chain management (SCM) applications delivered via software as a service (SaaS) models. Cloud computing is now recognized as a real game-changer, providing a route through which supply chain executives can rapidly and efficiently access innovative solutions—delivered through a SaaS model—and deploy them at scale. Driven by growing realization of the benefits these solutions provide, the SaaS for SCM market is predicted to grow by 24 percent in 2014, and reach a 19 percent compound annual growth rate to become a US\$4.4 billion opportunity by 2018.SaaS-based approaches work well when collaborative processes are involved [Kowalkiewicz, 2017]

Cloud computing adoption in supply chains is heavily dependent on the legacy ERP systems in place, as they provide the system of record corporate-wide. 56% of survey respondents have standardized on SAP ERP systems followed by Oracle (including PeopleSoft & JD Edwards) 16% and the remainder being multiple ERP systems.7% of respondents don't have an ERP system today.46% of respondents report that greater supply chain collaboration leads to problems being solved twice as fast. Cloud computing platforms are becoming more pervasive in large-scale supply chains as enterprises look to gain agility and speed in resolving complex problems through more effective collaboration.[Cegielski et al., 2012]

3. CLOUD COMPUTING: SUPPLY CHAIN AS A SERVICE

Flexibility being an important need of today's dynamic supply chains, it has seen an integration of cloud computing technology to combat it. Therefore, Supply Chain as a Service is an upcoming field of study.

Supply Chain as a Service will cater to the interaction of two or more stages/ parties of the supply chain for the flow of information and funds, by using the services provided by the cloud.

It's network of multichannel and interconnected businesses in the cloud involved in the end-to-end supply chain activities. Hence catering to the two way flow of the information, services and funds across the cloud from the supplier to the end customer.

Fig. 1. Cloud integrated end to end supply chain processes

This will enhance the working of companies in several ways. For startups, it will reduce the infrastructural investments which would in-turn help them to develop in shorter period of time. It will also increase the pace at which new services and products are introduced in the market. For the existing companies, this infrastructural benefit and the upcoming competition from them will make them re-invent their supply chain to constantly improve it. Thereby on a whole, making the supply chain more scalable and dynamic.

3.1 CYCLE VIEW OF SUPPLY CHAIN PROCESSES: A CLOUD BASED APPROACH

The processes that comprises of the supply chain are divided into a series of cycles each performed at the interface between two successive stages of the supply chain. Fig. 2 describes each cycle and the stages it connects. The efficiency and flexibility of each cycle of the supply chain can be increased by developing a cloud based infrastructure. The scope and capacity of each cycle on the cloud is discussed below.

Fig. 2. Cloud integrated end to end supply chain processes

1. **Procurement Cycle:** Through cloud computing ‘the total cost of ownership’ is reduced. This is because of the collaborative and accessible nature of the cloud based tools that optimizes the speed, cost and flexibility. It significantly reduces the burden on companies catering to thousands of suppliers on a regular basis. By creating a database of the suppliers on the cloud, contract management for each stage of the supply chain can be improved. Thereby leading to improved visibility all across the supply chain.
2. **Manufacturing Cycle:** The cloud technology can make the product design phase modular. This is by allowing individual setting while maximizing the performance of service. Even while manufacturing, it has high utilization in cases of highly fluctuating and flexible demand by planning and forecasting the manufacturing run.
3. **Replenishment Cycle:** The designed cloud based platforms helps companies to improve their service levels by coordinating the supply chain among partners. It can capture SKU wise spend data, performance based analytics, planning on the replenishment quantity and forecasting demand. These software can be used for- planning & allocating, assortment & space and replenishment. These collaborative planning and forecasting tools helps in reducing the Bullwhip effect across the supply chain. Apart from this, lead time can be controlled by Strong Service Level Agreements (SLAs) with the vendors. The inventory is optimized by having an optimum buffer for unpredictable demand.
4. **Customer order Cycle:** Effective management of customer data can be done by the use of the cloud technology. Enormous companies have various ways of providing customer service and managing orders. For the ease of this, cloud technology will help in the speedy aggregation and analysis of the customer data for their regular sales & promotion opportunities.

Also, one of the major areas where cloud computing can reduce the complexity of a supply chain is *Logistics*. Cloud computing applications for inventory management, transportation route planning, fleet management, global trade compliance, network strategy, warehousing and transportation are emerging. The main advantage of moving to the cloud is the ease of tracking of products/ services across the supply chain moving in both direction, either forward or backward (reverse supply chains). The recent development of the RFID (Radio- Frequency Identification) helps in tracking the product location and transmitting it back to the cloud. Hence, increasing the traceability in the supply chain.

In logistics, cloud technology is essential for 3PL companies for managing warehouse activities and planning of the optimum transportation route for different customers in one single system.

3.2 POSITIVE AND NEGATIVE IMPACT OF ADAPTING CLOUD COMPUTING IN SUPPLY CHAIN NETWORKS

POSITIVE IMPACT

Cost efficiency: It can be effectively used by firms in supply chain management with financial benefits. Here the

cloud services are provided by third party providers which reduce the investment, maintenance and upgrading costs. The capital costs are considered as a part of operational costs resulting in a net positive cash flow. The only costs that the firm pays is the activation cost and the usage fee as per requirements.

Simplification: A single platform is used to access all parts of the supply chain removing any compatibility and connection problems and enables all partners to share supply chain information in a single system. New members need just a set of password and surname to become a part of the collaborative committee. A single system reduces the response time of one partner to another's decisions. Hence, cloud services provide the basis for information control through a single centralized storage system ensuring the smooth flow of information.

Flexibility: A wide variety of applications can be hosted in a single cloud based platform. Access to the cloud can be made location independent by using common devices. This provides the supply chain the agility to introduce new products and services into the market.

Visibility: Timely connectivity among various supply chain participants is made possible through visibility. Visibility is an issue with 3PL services providers due to the absence of real-time inventory, shipment and logistics tracking. Cloud based systems eliminate this problem and provide for real-time tracking. These systems can act as virtual warehouses that enable strategic order fulfillment decisions and dynamic inventory re-routing decisions based on the actual product location.

Scalability: Cloud computing systems allow supply chain stakeholders to control their supply chain capacity according to demand fluctuations. In the absence of cloud, the stakeholders must hold the necessary database in order to meet customer demand and must hold an additional database just to meet excess demand for a short period of time. Cloud computing enables scaling and descaling according to demand forecasts.

Sustainability: There remains doubts on whether cloud computing really encourages sustainability. However, if many companies use the same cloud infrastructure, economies of scale can be leveraged to minimize the unit energy consumption.

NEGATIVE IMPACTS

Data Security and Privacy: Access to the cloud data should be limited to only authorized and trustworthy supply chain partners. Confidentiality can not be always ensured as these systems are vulnerable to hacking. Data acquisition by rival firms would pose an imminent threat to the whole supply chain.

Outdated Mindset: Sharing of data and information with the public represents a drastic change in the traditional culture business values. Many firms believe that keeping information about their supply chains or production processes provides them with a competitive advantage. Disclosure of such data to cloud systems instills the fear that this competitive advantage could be lost. Adoption of cloud systems implies a radical change in the business models incorporated in the whole supply chain network. Supply chain partners have to adapt their skill set to move from using common on-premises infrastructure to effectively use cloud systems. Such a transition is a time taking one.

Availability: Many firms are concerned with the crashing or disruption of cloud services. This is because these delays will directly affect a firm's supply chain operations and financial in turn, their financial welfare. Another concern is access to the cloud from different geographical locations with varying internet speeds.

Lack of Customization: Cloud services are often one size fits all. They do not fit specific supply chain operations and are hence avoided in the manufacturing industry where complex procedures are performed. A lack of customization could lead to a slow market response or even a loss of competitive advantage.

4. CONCLUSION

As mentioned above, there are both advantages and disadvantages of using the cloud technology for supply chain management. However as the potential benefits outweigh the limitations, it is recommended for firms to incorporate the cloud computing models effectively in order to collaborate and communicate among the supply chain stakeholders through the integration of supply chain activities. Therefore, companies that want to constantly improve and re-invent their supply chains should adopt cloud computing technology with consequent positive aspects.

Abstract: The rapid economic and industrial growth of highly populated developing/emerging nations is posing serious environmental and social problems not only in their own countries but also to the world. A growing number of organizations have begun or are willing to work towards implementing Green Manufacturing (GM) in these nations. But the adoption of GM is a challenge for the organizations in these nations as motivating factors (drivers) are not facilitated. The objective of this paper is to identify the enablers to implement green supply Chain and to understand their mutual relationship. Green supply chain management (GSCM) enablers are identified using available GSCM literature and on consultations with experts from industry and academician. Interpretive structural model (ISM) was developed to identify the contextual relationship among these enablers. This study will be helpful for both practitioners as well as academicians. The practitioners need to concentrate on identified GSCMEs more cautiously during GSCM implementation in their organizations and the top management could formulate strategy for implementing these enablers obtained through ISM and MICMAC analysis.

Keywords: Green Supply chain management (GSCM), GSCM enablers, Interpretive structural modeling, MICMAC.

1. INTRODUCTION

With the economic performance, the environmental performance has become increasingly important for organizations facing competitive, regulatory, and community pressures. With increased pressures for environmental sustainability, it is expected that enterprises will need to implement strategies to reduce the environmental impacts of their products and services (Zhu et al., 2005). To achieve the environmental performance, the organizations are trying to implement an environmental management system (EMS) over a last two decade. EMS has the primary purpose of preventing negative effects on the environment. This is achieved by developing environmental practices. The adoption of cleaner production processes, greener products, and measures of environmental performance also contribute to the successful implementation of an EMS. For the successes of EMS, the organizations should consistently strive for the reduction and elimination of all waste streams associated with the design, manufacturing, use and/or disposal of products and materials, maintaining air quality, etc. Till date, most of the organizations have implemented ISO 14000 system. ISO 14000 is the most widely accepted EMS certification accepted globally.

Over a last decade, the organizations and regulatory authority realized that, mere controlling the environment related issues insight the organization is not sufficient, and all the parties of SC should contribute to the same. The involvement of all the parties for environmental concern

can be treated as GSCM. For successful GSCM, a huge cooperation effort and the involvement of multiple actors are required, such as, from government to citizen, from organization to customers, and from organization to its suppliers. Therefore, selecting partners (suppliers, distributors, etc.) are an important step in creating a truly green and efficient SC.

The implementation of GSCM requires support of various factors like, employee environmental training, employee environmental empowerment, and employee environmental teamwork, training to suppliers and society, government support, cooperation with supplier and customer for eco-design, and cleaner production etc.

GSCM implementation requires identification of green supply chain management enablers (GSCMEs). Many researchers have discussed various GSCMEs which helps organization to achieve better organizational performance. But identifications of GSCMEs is not adequate, successful GSCM implementation requires identification of interrelationship between various GSCMEs and find out the GSCMEs having strong driving power (GSCMEs which helps to achieve other GSCMEs) and dependence power (GSCMEs which are largely dependent on other GSCMEs). The interrelationship between various GSCMEs and driving and dependence power can be obtained through interpretive structural modeling (ISM) model and Matriced' Impacts Croise's Multiplication Applique'e a' un Classement (MICMAC) analysis. In this paper, 14 GSCMEs have been

identified on the basis of literature review and the opinions of experts from academia and industry experts.

2. LITERATURE REVIEW

Governmental legislations, environmental concerns, and customer awareness, more and more industries are giving attention to green practices (Thomas and Bijulal 2011; Wang and Gupta 2011). Top management Commitment is necessary for supporting GSCM ideas, practices, and cooperation across organizational functions (Zhu et al. 2007), and success of any strategic program needs to be derived from top Management (Yu and Hui 2008). Top management has a significant ability to support actual formation and implementation of green initiatives across the organization. Top management may provide continuous support for GSCM in the strategic and action plans for successful implementation (Ravi and Shankar 2005; Mudgal et al. 2009). Trowbridge (2001) distinguished between internal and external drivers for the implementation of GSCM at a chip manufacturer. Internal drivers include the willingness to improve risk management due to potential interruptions in the supply chain, and the collaboration with suppliers to find alternative materials and equipment that minimize environmental impacts. External drivers include customers, investors and non-governmental organizations. The growth in this green supply chain literature extends back to the early 1990s with the advent of corporate environmental management, environmentally conscious manufacturing strategy, and supply chain management literature (Zhu and Sarkis, 2006). Previous research has identified that organizations can face a variety of barriers and enablers to sustainable SCM (Seuring and Muller, 2008), and that these can be either internal or external to the organization (Hervani et al., 2005; Walker et al., 2008).

Walker et al. (2008) reviewed the literature and identified the factors that drive or hinder organizations to implement green supply chain management initiatives; these includes internal drivers such as organizational factors, and external drivers such as regulation, customers, competitors, society and suppliers. Based on interviews conducted at seven different private and public sector organizations, they further identified the internal barriers such as cost and lack of legitimacy, as well as external barriers such as regulation, poor supplier commitment and industry specific barriers.

Rao and Holt (2005) observed that greening different phases of the supply chain leads to an integrated green supply chain, which in turn leads to competitiveness and better economical and operational performance. Wee and Quazi (2005) identified seven critical factors in their research into environmental management: top management commitment; total involvement of employees; training; green products/process design; supplier management;

measurement; and information management. Green purchasing has been an important issue since early 90's (Hwa, 2001). Green purchasing consists of involvement in activities which include the reduction, reuse and recycling of materials in the process of purchasing (Ninlawan et al., 2010). Reverse logistics is the process of retrieving the product from the end consumer for the purposes of capturing value or proper disposal (Ninlawan et al., 2010). Bowen et al. (2001) analyzed the relationship between supply management capabilities and green supply practices and identified internal drivers for implementing green supply policies (strategic purchasing and supply, corporate environmental pro-activity, and supply management capabilities.)

Interpretive Structural Modeling (ISM) can be used for identifying and summarizing relationships among specific variables, which define a problem or an issue (Warfield, 1974; Sage, 1977). It provides some means by which order can be imposed on the complexity of such variables (Jharkharia and Shankar, 2004; Ravi and Shankar, 2005; Faisal et al., 2006). GSCM also encompasses the collaboration-based approach. This approach includes training and education programs given to suppliers, environmental managerial information sharing, and collaborative research with suppliers (e.g., Vachon and Klassen, 2006; Min and Galle, 2001; Bowen et al., 2001; Lippman, 1999). Shang et al. (2010), explored key green supply chain management (GSCM) capability, six green supply chain management dimensions were identified: green manufacturing and packaging, environmental participation, green marketing, green stock, green suppliers, and green eco-design. Diabat and Govindan (2011), identified the drivers influencing the implementation of GSCM using an Interpretive Structural Modeling (ISM) methodology and extracted 11 drivers collected through past literature: Certification of suppliers' environmental management system; environmental collaboration with suppliers; collaboration between product designers and suppliers to reduce and eliminate product environmental impacts; government regulation and legislation; green design; ISO 14001 certification; integrating quality environmental management into planning and operation process; reducing energy consumption; reusing and recycling materials and packaging, environmental collaboration with customers; and reverse logistics. The common drivers are identified through the existing literature and with the combined assistance of company experts. The Common drivers are provided as competitors, stakeholders, company image, financial benefit, environmental conservation, customers and compliance with regulations.

Using available GSCM literature and on consultations with experts panel including 4 academicians and 5 experts from

industry working in the field of GSC, following 14 GSCME are indentified.

3. ISM METHODOLOGY AND MODEL DEVELOPMENT

ISM was first proposed by J. Warfield in 1973 to analyze the complex socioeconomic systems. ISM enables

individuals or groups to develop a map of the complex relationships between many elements involved in a complex situation. Its basic idea is to use experts' practical experience and knowledge to decompose a complicated system into several sub-systems (elements) and construct a multilevel structural model. ISM is often used to provide fundamental understanding of complex situations, as well as to put together a course of action for solving a problem.

The methodology of ISM modeling adopted from Ref. Gorane and Kant (2013).The various steps involved in the ISM methodology are as follows:

3.1. Structural Self-Interaction Matrix (SSIM)

A group of experts, from industries and the academics was consulted in identifying the nature of contextual relationships between the QEEs. For analyzing QEE in developing SSIM, the following four symbols have been used to denote the direction of the relationship between the QEEs (i and j):

V - GSCME i lead to achieve GSCME j;

A - GSCME j lead to achieve GSCME i;

X - GSCME i and j lead to achieve each other; and

O - GSCME i and j are unrelated.

TABLE 3: Structural self-interaction matrix (SSIM)

GSCME Code	14	13	12	11	10	9	8	7	6	5	4	3	2
GSCME1	V	V	V	V	V	V	V	V	X	V	V	X	X
GSCME2	V	V	V	V	V	V	V	V	X	V	V	X	
GSCME3	V	V	V	V	V	V	V	V	X	V	V

GSCME5	V	V	V	V	V	V	V	V	A				
GSCME6	V	V	V	V	V	V	V	V					
GSCME7	V	V	V	V	V	V	V						
GSCME8	V	V	V	A	X	X							
GSCME9	X	V	V	A	X								
GSCME10	V	V	V	A									
GSCME11	V	V	V										
GSCME12	X	V											
GSCME13	A												

3.2 Initial and Final Reachability Matrix

The SSIM has been converted into a binary matrix, called the initial reachability matrix (see Table 2) by substituting V, A, X and O by 1 and 0. By incorporating the transitivity, the final reachability matrix obtained

3.3. Level Partitions

From the final reachability matrix, the reachability set and antecedent set for each GSCMEs are found. The reachability set includes GSCME itself and others which it may help to achieve, similarly the antecedent set consists of GSCME itself and the other GSCMEs which help in achieving it. Then, the intersection of these sets is derived for all GSCME. The GSCMEs for which the reachability and intersection sets are same is the top-level GSCMEs in the ISM hierarchy. The top-level GSCMEs in the hierarchy would not help achieve any other GSCMEs above its own level. Once the top-level GSCMEs are identified (Table 6), it is separated out from the other GSCMEs.

TABLE 6: Partitioning of reachability matrix: first iteration

GSCME Code	Reachability Set	Antecedent set	Intersection set	Level
GSCME1	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14	1, 2, 3, 6	1, 2, 3, 6	
GSCME2	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14	1, 2, 3, 6	1, 2, 3, 6	
GSCME3	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14	1, 2, 3, 6	1, 2, 3, 6	
GSCME4	4, 5, 7, 8, 9, 10, 11, 12, 13, 14,	1, 2, 3, 4, 6	4	
GSCME5	5, 7, 8, 9, 10, 11, 12, 13, 14	1, 2, 3, 4, 5, 6	5	
GSCME6	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14	1, 2, 3, 6	1, 2, 3, 6	
GSCME7	7, 8, 9, 10, 11, 12, 13, 14	1, 2, 3, 4, 5, 6, 7, 11	7	
GSCME8	8, 9, 10, 12, 13, 14	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11	8, 9, 10	
GSCME9	8, 9, 10, 12, 13, 14	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11	8, 9, 10	
GSCME10	8, 9, 10, 12, 13, 14	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11	8, 9, 10

GSCME13	13	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14	13	I
GSCME14	12, 13, 14	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14	12, 14	II

3.4 Building the ISM mode

Structural model is generated using final reachability matrix (Table 5), If there is a relationship between the GSCMEs i and j, this is shown by an arrow which points from i to j. This graph is called a directed graph, or digraph. After removing the transitivity the digraph is finally converted into the ISM-based model (Figure 1).

Fig. 1. ISM Model Formulation for GSCM Enablers

4. FINDINGS AND DISCUSSIONS

It has been found that GSCM implementation has become an essential prerequisite to staying in the global competitive market. Though the organizations are benefitted by GSCM implementation, but implementing GSCM in an organization is challenging and difficult or costly to implement. A range of GSCMEs can help it to achieve successful GSCM implementation.

The main objective of this research work is to identify and find out the interdependencies among all selected GSCMEs and further to analyse the driving and dependencies of GSCMEs for successful GSCM implementation in the organization. To achieve these objectives, ISM-based model and MICMAC analysis have been deployed in order to understand the interactions among different GSCMEs completely so that management may lay stress more on enablers which are more effective for GSCM implementation. This will help to improve organizational performance and productivity in the organization and thus

will help in improving customer satisfaction. In this paper, 14 GSCMEs have been identified on the basis of literature review and the opinions of experts from academia and industry experts. The interrelations between the various GSCMEs were obtained from academicians and group of industry experts.

ISM is used by various researchers for modelling the GSCM variables for improving the GSC performance. ISM technique has been applied to many areas of GSCM like ISM in vendor selection, Reverse logistics, IT implementation, GSC performance measurement and so on. However, a major contribution of this research lies in the development of linkages among various GSCMEs for entire GSC through ISM and MICMAC analysis. In this research, the ISM MICMAC approach is used as; ISM provides only binary relationship between identified variables; while the MICMAC approach provides sensitive analysis related to driving and dependent behaviour of GSCMEs.

The other objective of this paper was to analyze the driving and dependence power of the GSCMEs that influence the GSCM implementation in an organization through MICMAC analysis. In MICMAC analysis the GSCMEs are classified into four clusters (Figure 2). The first cluster consists of the autonomous GSCMEs that have weak driver power and weak dependence. These GSCMEs are relatively disconnected from the system, with which they have only few links, which may be strong. Second cluster consists of the dependent GSCMEs that have weak driving power but strong dependence. Third cluster has the linkage GSCMEs that have strong driving power and also strong dependence. These GSCMEs are unstable and any action on these GSCMEs will have an effect on others and also a feedback on themselves. Fourth cluster includes the independent GSCMEs having strong driving power but weak dependence. The analysis of MICMAC is as follows.

4.1 Autonomous GSCMEs

The driving-dependence power diagram shows that there are no autonomous GSCMEs in the process of GSCM implementation. Autonomous SCMEs are weak drivers and also weak dependent. The autonomous GSCMEs are relatively disconnected from the system. Hence, they do not have much influence on the system. Therefore, among the 14 selected GSCMEs, all the SCMEs have much influence in the GSCM implementation.

4.2 Dependent GSCMEs

GSCME1, 2, 3, 4, 5, 6, 7, 11 are weak drivers but are strongly dependent on others (Figure 2). They are seen at the top of the ISM hierarchy (Figure 1), therefore considered as important GSCMEs. Their strong dependence indicates that they require all the other GSCME to minimize the effect of these GSCMEs during GSCM implementation. The management should therefore accord high priority in tackling these GSCMEs.

4.3 Linkages SCMEs

There is no GSME in this linkage category that has a strong driving power and also a strong dependence (Figure 2). Any change occurring to these GSCMEs will have an effect on others and also a feedback on themselves. Hence, these GSCMEs are unstable in nature which may affect the successful GSCM implementation in the organizations.

4.4 Independent GSCMEs:

The driving power and dependence diagram (Figure 2) indicates that independent GSCME8, 9, 10, 12, 13, 14 having less driving Power and more dependence power. Thus, management needs to address these GSCMEs more cautiously and may be treated as the root cause of all the GSCMEs. It has been observed that these GSCMEs help to achieve GSCMEs which appear at the top of ISM hierarchy.

Fig. 2. MICMAC Analysis

5. CONCLUSIONS AND SCOPE FOR FUTURE RESEARCH

GSCM implementation is tough task due to the complexity of GSCM practices, customer awareness and increase in cost of product and regulation. Decision makers must be aware of the relative importance of the various drivers and the techniques for implementing them. This paper has identified 14 key GSCMEs by reviewing a number of research articles. It is moreover evident that no single GSCMEs would be self-determining for GSCM implementation in an organization, therefore, it becomes more important to identify the relationship of GSCMEs with each other. ISM methodology is used to develop relationship among various GSCMEs for each dimension of GSCM implementation. MICMAC analysis is carried out to identify the driving and dependence power of GSCMEs using ISM result.

In this research work, integrated model of GSCMEs is developed using ISM and MICMAC approach, which may be helpful to GSC managers to employ this model in order to identify and classify the important GSCMEs for their needs and to reveal the direct and indirect effects of each GSCME on the GSCM implementation. The finding of paper provides important guidelines for both practitioners as well as the academicians. ISM model identifies the hierarchy of actions to be taken by practitioners in order to maximize the effect of these GSCMEs in order to implement GSCM successfully. The MICMAC analysis indicates the category of the GSCMEs which needs attention by practitioners according to their dependence power and driving power. Practitioners should concentrate on those GSCMEs which have higher driving power because these GSCMEs should be emphasized for effective and successful GSCM implementation. These higher driving GSCMEs are root cause for the other GSCMEs which have higher dependence. Once these higher driving power GSCMEs are identified, the top management could formulate strategies for enhancing their effects during GSCM implementation.

ISM model development and MICMAC are obtained through the judgments of academicians and few industry experts. Any biasing by the person who is judging the GSCMEs might influence the final result. Hypothesis testing, structural equation modeling (SEM) and case studies may be carried out to validate the model.

E-commerce: Past, Present and Future - An Indian Perspective

Hemantkumar P. Bulsara, Pratiksinh S. Vaghela

Department of Applied Mathematics and Humanities,
S.V. National Institute of Technology, Surat, Gujarat, India

Abstract: Internet and its associated information technologies significantly transformed the way we live our life. It touches every aspect of our life and one of the aspects is our purchasing habit. This report mainly focuses on retail E-commerce or B2C (Business to Consumer). Since inception earlier in 1995, E-commerce is enjoying the era of explosive growth. This paper deals with the introduction of E-commerce, its definitions, the difference between E-commerce and E-business, E-commerce organizations and its classification based on types of transactions and involved parties and benefits of E-commerce to organization and consumer. Further, it gives an overview of evolution of E-commerce at global as well as India level. E-commerce current scenario with major statistics, leading E-commerce models discussed in chapter three. Apart from this, the paper discussed key drives of E-commerce in India. It gives an idea about key challenges faced by E-commerce industry in India and highlights of future trends of E-commerce in India. Finally, Conclusion and recommendations are discussed.

Keywords: E-commerce, Past, Present, Future, opportunities, Challenges, India

1. INTRODUCTION

The Internet has changed the way live our life. Every minute of our life is augmented by its use for sharing our view, virtual engagement on social networking site, digital entertainment, marketing and even buying and selling. If organizations want to take advantage of latest Internet technologies, then they should take the strategic initiative. One of the most significant areas where the company can focus is E-commerce. Electronic commerce is a revolutionary era which is growing and continuously changing the way business has been managed. Moreover, it becomes the base for a new form of business around the world. Further, Industry value chain is redefined by E-commerce and blow the bugle for the new complex competitive environment. Looking into these scenarios, organizations are going to face immense pressures and challenges due to economic reforms towards new digital/virtual markets. Organizations need to keep up with this groundbreaking changes which have the capacity to transform the whole economic infrastructure. If organization wants to endure then they have to develop awareness and understanding about the constantly progressing and growing complex environment of E-commerce to compete globally. Along with this tremendous growth in Smartphone, tablet, lightweight laptop prompted a new E-commerce platform called Mobile commerce (M-commerce) and Social commerce (S-commerce).

What is E-commerce

When we think of E-commerce the first thing comes in our mind is Amazon, Flipkart – an online shopping websites for retail goods. In simple since E-commerce means to buying

and selling on the internet. The definition of E-commerce in the modern times implies that a transaction is termed as electronic commerce if it typically uses the World Wide Web at least at any point in the transaction's lifecycle[2]. According to UK government "E-commerce is the exchange of information across electronic networks, at any stage in the supply chain, whether within an organization, between businesses, between businesses and consumers or between the public and private sector, whether paid or unpaid" (Cabinet Office, 1999). Another definition is given by AMA Electronic commerce or E-commerce refers to a wide range of online business activities for products and services[3]. E-commerce refers to various online commercial activities focusing on commodity exchanges by electronic means, Internet in particular, by companies, factories, enterprises, industrial undertakings and consumers[4]. The government of India defines E-commerce as buying and selling of goods and services including digital product over the digital and electronic network (DIPP 2016). These definitions signify that electronic commerce is not solely restricted to the actual buying and selling of products, but also includes pre-sale and post-sale activities across the supply chain. Since E-commerce is a brand new science, it is not at all surprising that there are various definitions about it.

2. EVOLUTION OF E-COMMERCE – INDIA

E-commerce has its existence in India since last 15 years. It was only a topic for discussion in India until in 1999 Reiff.com added India's first online shopping platform to its portal followed by the launch of Bazee.com in 2000 and the journey of E-commerce (Table I) begins.

TABLE I: Evolution of E-commerce Timeline (India)

Timeline	Historical Event
1999	Rediff.com added online shopping to its portal
2000	Bazee.com was launched which had the good response from Indian customer. In 2004 it was acquired by eBay
2002	The Indian government launched IRCTC – an Online Passenger Reservation System
2003	Airlines in India followed the Indian railways and introduce online air ticket booking system
2005	Makemytrip.com, Started its operations in India by providing online flight ticket to travel and then after extended in holiday packages and hotel booking
2006	Yatra.com launched to provide online flight ticket booking services
2007	Bookmyshow.com entered and become the largest entertainment ticketing website. At the same time, B2C based E-commerce started in India by the introduction of Flipkart.com with its discount model
2009	Myntra.com was launched, it selling the retail fashion and lifestyle products to Indian customers. At the same time, Mydala.com was started. It was India's first group buying site like Groupon
2010	Its time for snapdeal.com in India. Started and daily deals platform which becomes an E-commerce company via marketplace model
2011	BuildaBazaar.ooo created e platform for small Indian seller by providing the self-service portal where a user can create e-store, upload product catalog, customize the site and sell their product. At the same time Groupon enter in India by acquiring SpSaSta.com and first re-branded it as “Crazeal” then “Groupon India, now ‘nearbuy.com’”
2012	An Indian fashion and lifestyle portal Jabong.com was launched
2013	Amazone.in was launched in Indian started with electronic and extended with fashion, beauty, home essential and health care categories
2014	Flipkart.com acquired Myntra.com in an estimated Rs. 2000 cr.

3. E-COMMERCE IN INDIA

India's GDP is expected to increase 7.6% in 2017 and it is expected to increase to 8.1% in 2018[12]. This will lead to more domestic as well as foreign investment in growing

sectors of India. The retail sector is growing at 11% CAGR and estimated to US\$600 billion in 2016 to US\$1 trillion in 2020. Even though total E-commerce in India accounts only 2% of total spending on retail, E-commerce is becoming the key factor to create the new market which previously unreachable. There are significant infrastructural changes happening in Indian economy with respect to rapid adoption of advanced technology that supports the growth of E-commerce. Technological adoption in India is high especially in Smartphone segment due to affordable and easy to use features. India became the second largest country after China for Smartphone penetration with 220 million users in 2016. Moreover, during the same time, internet penetration is also significantly rising with the number of internet users at 354 Million as of September 2015. In addition to this, there is a shift in mobile usage from voice to data. Mobile internet spend has risen from 54% to 64% from 2014 to 2015. This is due to an availability of high-speed 3G & 4G internet connectivity at affordable prices which has led to an increase in transactions done via mobile[13]. Further, India's rank for ease of doing business went up by 4, from 134 to 130 in just one year[14]. India rank 39th among 138 countries on global competitiveness index has jumped by 16 ranks from 55th rank in 2015 which indeed a significant improvement for India[15] and that is because of the improved regulatory framework that creating a conducive business-friendly environment. These factors are going to have the positive impact on foreign investment in India.

This above positive indicator leads foreign and domestic investments in India mainly in E-commerce industry which is expected to be a value of US\$101.9 billion in 2020. Further due to other infrastructural development in terms of Digital advertisements, Logistics, Digital payment, Finance support, Technology and training to MSMEs for E-commerce platform enable faster growth rate of E-commerce in India.

TABLE II: E-commerce in India and its future predictions

India - E-commerce (Only B2C)	2015	2020*
Total E-commerce size	US\$16 billion	US\$101.9 billion
Online shopper as a % of internet user	11%	36%
Number of online shopper in India	39 million	220 million
Average spend per online shopper in India	US\$247	US\$464

TABLE III: Indicative list of current leading E-Commerce models in India

E-commerce Models	Leading companies
B2C E-commerce marketplace	Snapdeal.com, Amazon.com, Flipkart.com
B2C E-commerce inventory led	BigBasket.com, FirstCry.com, Zovi.com
B2C E-commerce Aggregator	Uber.com, olacabs.com
C2C E-commerce	Cloudacar.com, quickr.com, olx.in
B2B E-commerce	Mjunction services limited (metal junction, coaljunction, buyjunction, etc.), cloud Buy.com, tolexo.com, industrybuying.com, power 2sme.com, Amazonbusiness.com
Omni-channel retailer	Shoppers Stop Ltd., Infiniti Retail Limited Croma, Raymond Limited
<i>Source: CII report: e-Commerce in India -a Game Changer for the Economy 2016[13]</i>	

TABLE IV: Indicative list of emerging Vertical Specific E-Commerce companies in India

E-commerce Models	Leading companies
Online Travel	Makemytrip.com, yatra.com, cleatrip.com, goibibo.com
Online Real Estate	Magicbricks.com, 99acres.com, commonfloor.com, Housing.com
Online Fashion	Jabong.com, Myntra.com, Zovi.com, yepme.com, limeroad.com
Online Furniture	Fabfurnish.com, Pepperfry.com, urbanladder.com
Online Education	Purple Squirrel Eduventures, Plancess.com
Online Food and grocery	Zomato.com, Foodpanda.in, TinyOwl.com, BigBasket.com, Grofers.com

TABLE V: Indicative list of emerging Online Aggregator Models in India

E-commerce Models	Leading companies
Online Health	Portea.com, Healthkart.com,
Online Laundry	Wassupondemand.com, DoorMint.in, LaundryWala.co.in
Online Entertainment	Netflix.com, ErosNow.com, Hooq.com
Online Truck Booking	TruckSuvridha.com, TruckMandi.in, The Karrier.com, Fortigo.com

Source: CII report: e-Commerce in India -a Game Changer for the Economy 2016[15]

Based on Gross Merchandise Value most of the global E-commerce companies shows the low profit in spite of having the presence for 5 to 20 years. This scenario continues in India i.e. Indian E-commerce companies showing growth in terms of GMV but overall incurring losses. On the other hand trend is different in the B2B segment in India. B2B market Valued at \$300 billion in 2014 and expected to reach at \$700 billion by 2020 in India. The profit margin, volume of purchase, importance of quality rather than price and lack of heavy discount are the few reasons attributed for B2B segment profitability.

The Government has allowed 100% FDI through automatic route in B2B E-commerce and 100% FDI under automatic route is permitted in Marketplace model of E-commerce. FDI is not permitted in inventory led based model of E-commerce. FDI in B2C is permitted in following conditions. 1) Manufacture is permitted to sell its product manufactured in India through E-commerce retail. 2) A single brand retail trading entity operating through brick and mortar store is permitted to undertake retail trading through E-commerce. 3) An Indian manufacturer is permitted to sell its own single-brand products through E-commerce retail. Indian manufacture would be the investee company, which is the owner of the Indian brand and which manufactures in India, in terms of value, at least 70% of its product in-house, and source, at most 30% from Indian manufacturers[16].

B2B, B2C, C2C, and Omni-channel retailer models currently exist and emerging E-commerce models (Table III & IV) in India. Basically, B2C further can be classified as Marketplace Model; Investor led Model and Aggregator Model. Vertical specific E-commerce (Table V) companies are also emerging in Traveling, Fashion, Real Estate, Furniture, Educational and Food-Grocery segments. E-commerce Aggregators (Table 6) digitizing several offline services and creating a convenient ecosystem and online platform in the area of Health, Laundry, Entertainment and Truck booking. Online Aggregators besides providing the comparison of price and features across service providers are also connecting buyers directly with sellers, thus reducing costs to consumers by obviating middle-men.

4. KEY CHALLENGES OF E-COMMERCE INDUSTRY IN INDIA

The e-commerce industry is enjoying above mentioned drivers that boosting the growth and acceptance of E-commerce in India. However, there are many challenges encountered by the E-commerce companies. These challenges (Table VI) are mainly related to Infrastructural support, Customer acquisition, satisfaction and loyalty, Government policies and legal framework and scaling and profitability of organization etc.

TABLE VI: List of Key Challenges faced by B2C E-commerce industry in India

Key Challenges	
Cash on Delivery (CoD) as a mode of payment	Customer's preference for CoD increases chances of return and results in locking up of working capital for both the platform and the sellers.
Network and bandwidth dependency	Access to E-commerce platforms, through desktops, mobiles, and other devices are dependent on the network bandwidth.
Merchant's lack of online experience	Small merchants are uncomfortable and unfamiliar with technology and need to be trained on the use of E-commerce technology.
Digital payment transaction failure	Due to lack of high-speed bandwidth and inefficiencies in payment gateway technology, the E-commerce industry is facing high transactions failure rates leading to customers dissonance
Dependence on Telecom Operators for rural penetration Navigating Procurement Process of companies	E-commerce companies, who want to expand into tier II & III cities, are dependent on the Telecom Operators to roll out 3G/4G into such areas for connectivity.
Logistic and Reverse logistics	Poor supply chain infrastructure in tier I and II cities are creating the problem for last mile delivery. Currently, reverse logistics is highly inefficient, which results in high inventory and increased costs. Apart from this what about customer delivery experience is still the question mark.
Lack of customer loyalty	Currently, customers are mainly attracted through discounts and have very little brand loyalty. Customers easily and frequently switch among platforms based on

	best discount offered by them.
High cost of customer acquisition	Intense competition and heavy discounting have resulted from customer acquisition and retention costly for E-commerce companies.
Scaling and profitability of organizations	B2C E-commerce companies have raised and infused capital from investors to scale operations. However, from a profitability perspective, the losses have grown faster than sales. Majority of the companies rely on discounting for customer acquisition leading to an absence of long-term sustainable business models.
Tax framework	Due to the absence of a uniform tax structure, States have adopted different tax frameworks and Inter-State goods movement is a challenge. It not only increases operational and compliance costs but also delays timely delivery of goods.
Security and Counterfeit products and services	There is an increasing incidence of cyber thefts and payment thefts in the industry today. Additionally, the supply of fake, counterfeit products by the merchants on the platform is on a rise.

5. FUTURE OF E-COMMERCE IN INDIA

5.1 E-commerce Predictions

Future of E-commerce is bright and fascinating (Table VII) globally as well as in Asia. Same case with the India, where total B2C sales are US\$24.61 Billion in 2016 and projected to reach US\$68.47 Billion by 2019 which will be still only 4.8% of total retail sales. India is the 3rd largest country in terms of having the number of digital buyers that is 112.7 Million in 2016 which likely to reach 239.7 Million by 2019 which will be still only 24.3% of total population in 2019.

TABLE VII: B2C E-commerce industry current size (2016) & growth prediction (2019)

B2C E-commerce industry size – World, Asia, and India (US\$)		
Worldwide Total B2C sales	\$2.050 Trillion (2016)	\$3.578 trillion (2019)
Worldwide total B2C % of total retail sales	8.6%	12.8%
Asia-Pacific Total B2C sales	\$1, 152.21 Billion	\$2, 336.27 Billion

Asia-Pacific total B2C % of total retail sales	12.4%	20.4%
India total B2C sales	\$24.61 Billion	\$68.47 Billion
India total B2C % of total retail sales	2.6%	4.8%
India B2C sales growth rate	75.8%	23.9%
Worldwide Digital buyers	1.61 Billion	2.07 Billion
Asia-Pacific Digital buyers (share worldwide)	812.2 Million (50.4%)	1139.6 Million (55.1%)
Asia-Pacific Digital Buyer Penetration (% of internet users)	54.8%	62.0%
Asia-Pacific Digital Buyer Penetration (% of population)	25.4%	34.7%
India Digital buyers (3rd rank)	112.7 Million	239.7 Million
India Digital Buyer Penetration (% of internet users)	43.8%	64.4%
India Digital Buyer Penetration (% of population)	12.0%	24.3%
Source: eMarketer 2016 report on worldwide retail e-commerce sales.[9]		

6. CONCLUSION AND RECOMMENDATIONS

Indian E-commerce industry is growth stage and showing tremendous potential. E-commerce begins its journey in 1999 and today, in 2016 it becomes the fastest growing industry (Growth rate 75.8% - 2016 eMarketer) of India. The Higher rate of Internet and Smartphone penetration, availability of 3G and 4G connectivity and improvement of doing business rank of India further promotes investment in E-commerce industry in India. Presently, in India Inventory led and Marketplace are two model of B2C E-commerce exist. Apart from this B2B, C2C and Omnichannel retailers are also growing. Vertical specific E-commerce model and Online Aggregators model of E-commerce is also emerging. The growth that has been seen by the E-commerce industry is accountable to significant changes happening in Indian economy which support the growth of E-commerce in India. These changes include Governmental policy development and initiative like Digital India, Start-up India, Innovation Fund, Skill India, Make in India, Goods, and Service Tax etc., Internet and smart penetration, New Digital Payment Solutions, logistic support are acting as a key driver for the growth of E-commerce industry.

The Indian government is working on infrastructural and legal issues whereas for profitability and scaling of the organization largely depend on how E-commerce company managing their customers. This is true same for the high customer acquisition cost and high preference for CoDs. Using services of new startups in the logistic sector, acquiring logistic companies and backward integration by E-commerce can be the solution for last mile delivery problem in India. Further, combined efforts of government and industry can bring the boost to the adoption of new payment methods which might migrate payment from cash to card payment and from card to digital and mobile payment. Wallet space is emerging to support online payment by creating the secure option for payment to gain

the trust of customers. Effective acquisition and retention of the customer by finding faster and innovative solutions to the challenges faced by E-commerce industry will be the key to success. E-commerce Company needs to understand customer online shopping adoption and issues related to it and enhance customer purchase experience to generate the higher rate of loyalty and satisfaction for emerging market in Tier II & III cities of India. Taking futuristic approach E-commerce companies now need to focus more on service aspect by shifting from discount model to business model and should think in the direction for creating and sustaining strong brand of itself.

The Growing Challenges Of Indian E Commerce What You Need To Know-RupakAgarwal - BW Business world, <http://businessworld.in/article/The-Growing-Challenges-Of-Indian-E-Commerce-What-You-Need-To-Know/10-01-2016-90121/>, retrieved on 26/11/2016

Supply Chain Management Practices in Industry

P.C. Shete, S.P. Mogal

Department of Mechanical Engineering
NDMVPS's KBT College of Engineering, Nashik, Maharashtra, India

Abstract: Sustainable Supply Chain Management (SSCM) has attracted considerable interest among industries. The aim of paper is to present a critical review of the literature, to discuss for the use of SSCM through a framework, and suggest further research directions. It is observed that environmental and social performance have a positive relationship with economic performance. The present study has several practical implications which would enable managers to adopt sustainable practices in their supply chain. Sustainable supply chain management (SSCM) is now identified as a primary factor in promoting industrial sustainability. SSCM effectively manage the material, information and capital flows associated with the procurement, production and distribution of products or services to fulfil short term and long term profitability.

Keywords: Sustainable Supply Chain Management (SSCM), Green supply chain management (GSCM), Industry

1. INTRODUCTION

Increased competition at the supply chain level, rapid changes in customer demand patterns and pressures from governments and other stakeholder groups has encouraged most companies to increase its attention on adoption of sustainability practices. Supply chain interferences may benefit a company's unaffected competitors. However, market conditions may affect companies within an industry in a similar way. Many industry competitors share suppliers, transporters, and manufacturers, indicating that interferences at one company may have negative consequences for the competitors.

Ashby et al. (2012) and Halldorsson et al. (2009) have discussed that the word 'sustainability' is over stretched and it may be that the level of attention is raised by unnecessary inflation surrounding sustainability in supply chains. Beske and Seuring (2014) have discussed that a sustainable supply chain differs from a conventional supply chain. There is also strong evidence suggesting that sustainability in supply chain networks has helped organizations to achieve better performance (e.g. Tsoufas and Pappis, 2006; Yusuf et al. 2013; Plambeck et al. 2013). Few empirical studies are available on sustainability, most of them primarily focus on environmental practices (Govindan et al., 2015; Chen et al., 2015; de Giovannia & deVinzi, 2012). On the other hand, there are significant number of empirical studies that concentrates only on the social dimension of sustainability (Bai et al., 2015; Hutchins & Sutherland, 2008; Baske et al., 2008). Further, there are studies that investigate only the economic aspect of sustainability (Avami, 2013; Bottani & Rizzi, 2008; Turkay et al., 2004; Rao & Holt, 2005; Gunasekaran et al., 2001). However, in order to have a whole and broad understanding of the mechanisms involved in a sustainable supply chain, studies should be carried out that consider all dimensions of sustainability (Jakhar, 2015;

Silvestre, 2015). Implementation of sustainable practices in supply chains is fraught with several challenges. These challenges lead to negative impacts particularly during initiation stage of sustainability practices (Faisal 2010; Zaabi, Dhaheri, and Diabat 2013). automobile supply chain has a significant role in sustainable development.

Recent changes in global economy resulted; India is becoming one of the cheapest sourcing in the automotive map edging out knowing competitors like China, Mexico and Eastern Europe. In line with this, many multi-national industries (BMW, FORD, NISSAN) have identified India as a potential market for strong product growth and have started investing heavily by setting up manufacturing facilities and distribution centers (Mathiyazhagan and Noorul Haq 2013; Xu et al. 2013).

2. LITERATURE REVIEW

There are various concepts, definitions and overlapping views among the researchers and practitioners, but the central theme is still the same for all of them. Many researchers have approved upon high level of importance to the knowledge flow. Knowledge flow improves organisational performance through enabling communication between various stakeholders of organization. Reviews of the literature on the definitions of SSCM (Carter and Easton, 2011; Ahi and Searcy, 2013; Pagell and Shevchenko, 2014) propose that SSCM is the voluntary integration of social, economic and environmental considerations with the key inter organizational business systems to create a coordinated supply chain to effectively manage the material, information and capital flows associated with the procurement, production and distribution of products or services to fulfil short term and long term profitability, stakeholder requirements, competitiveness and resilience of the organization. Pagell and Schevchenko (2014) have

discussed that SSCM could be understood from a process point of view and in particular from a cycle and push/pull view. The cycle view focuses on embracing sustainability in procurement processes, manufacturing processes, replenishment processes and executing customer order processes. We can argue that the push/pull interface focuses on collaboration between suppliers and manufacturers. Therefore, SSCM can be understood as SCM focusing on maintaining environmental, economic, and social stability for long-term sustainable growth. Collaboration helps to commercialize and to ensure easy access to innovative technologies for the local and lower-tier suppliers in the supply chain (Vachon and Klassen, 2008; Dam and Petkova, 2014; Glover et al., 2014). Further, Chiou et al. (2011) discussed the impact of environmental collaboration of internal processes' environmental sustainability referring to benefits such as clean technologies, lower energy consumption, and material re-use. Grekova et al. (2016) suggest that environmental supplier collaboration can enhance the significant firm's performance both directly (Zhu et al., 2007; De Giovanni, 2012) and indirectly (Dyer and Singh, 1998), that is, by stimulating the firm to invest in and implement more sustainable processes that influence the firm's performance. Thus, we argue that strategic supplier collaboration is acute for the success of SSCM, and is considered as one of the drivers of SSCM. Colicchia et al. (2016) proposed a supply chain network design framework which involves the environmental impact of both transportation and warehousing activities in chocolate products. It was found that cost-driven network optimization may lead to beneficial effects for the environment with minor increase in distribution costs. The incremental cost can be offset by improving the environmental performance. Luthra, Garg and Haleem (2015) identified critical success factors (CSFs) and performance measures of green supply chain management (GSCM). Marshall et al. (2014) developed multidimensional conceptualization and measure of social and environmental supply chain management sustainability practices. Tappia et al. (2015) suggested a model to evaluate the energy consumption and environmental impact of automated warehousing solutions. Savino, Manzini, and Mazza (2015) discussed the integration of environmental concepts in the value chain approach, with a concurrent assessment of sustainability improvements and their economic impact of fruit supply chain. Gopal and Thakkar (2016) analysed sustainable supply chain (SSC) management practices using SEM for understanding the causality among the TBL dimensions (financial, social and environmental) for Indian automobile industry. Jia et al. (2015) analyzed and identified dominant SSCM practices in the mining and mineral industries using Interpretive structural modelling (ISM). Wuet al. (2016) proposed a comprehensive and quantitative method to understand the concept of SSCM and to assess its performance. Dubey et al. (2016) highlighted alternative methods research for

SSCM by providing a conceptual framework that explores SSCM drivers and their relationships. Esfahbodi et al. (2016) address the trade-offs between environmental and cost performance in SSCM especially in emerging economies. Ahmad et al. (2016) reviewed corporate sustainability reporting practices in accordance to SSC oil and gas industry. Ahmad et al. (2016) focused on the challenges in relation to the SSCM practices in industries. Esfahbodi et al. (2016) summarized the role of governance in the adoption of SSCM practices and investigated the performance gains of an organization with regard to both environment and economy. Hussain et al. (2016) provided a comprehensive framework on sustainability measurement with a practical approach for measuring and implementing SSCM practices in Arab countries. It is thus clear that many researchers have focused on the need for implementation of SSCM in firms, the benefits of adopting SSCM practices, and the impact of those practices on a firm's performance (Jia et al., 2015; Luthra et al., 2017). Wolf (2011) has argued that sustainability in supply chain networks can be achieved through appropriate collaboration. Sustainable supply chain management (SSCM) is now identified as a primary factor in promoting industrial sustainability (Tonelli, Evans, and Taticchi 2013). Gopal and Thakkar (2015) has revealed that adoption of environmental practices in Indian automobile organizations such as reduction of energy consumption, resource consumption, emissions and solid waste can result in significant improvements in their economic performance.

Wuet al. (2016) proposed a comprehensive and quantitative method to understand the concept of SSCM and to assess its performance. Ahmad et al. (2016a) reviewed corporate sustainability reporting practices in accordance to SSCM in the oil and gas industry. Ahmad Et al. (2016b) focused on the challenges in relation to the SSCM practice in industries. Govindan et al. (2014) analyzed the impact of SSCM practices using a three-dimensional deductive research based approach; they considered the three dimensions of sustainability through lean, resilient, and green supply chain management paradigms. Beske et al. (2014) critically analyzed SSCM practices associated with the food Industry and summarized how the practices allow companies to gain control over their supply Chain and to achieve a competitive advantage.

Ahi and Searcy (2013) have argued that SSCM is an extension of green supply chain management (GSCM) with the integration of social and economic factors along with environmental factors. GSCM is relatively new concept, which is gaining popularity among manufacturers and suppliers to improve the organizational environmental performance (Sarkis et al., 2011; Chang et al., 2013; Madaan and Mangla, 2015). GSCM has been recognized as a crucial part to encourage organizational sustainability (Sarkis et al., 2011; Rath, 2013). Research on GSCM has

been attracting keen interest across the globe in last few years and the same has recently grown in India (Mohanty and Prakash, 2014; Mangla et al., 2014; Luthra et al., 2015).

3. CONCLUSION

Analyze sustainable supply chain (SSC) management practices for industry and to identify the critical factors for its successful implementation. SSC has been frequently promoted as a means of improving business competitiveness. Indian automobile industry, faced with intense supply chain competition and rapid changes in customer demand patterns and pressures from governments and other stakeholder groups has been encouraged to increase its attention on adoption of sustainability practices. Sustainability has become a competitive advantage of the individual firm's supply chain. Critical Success Factors (CSFs) to implement Green Supply Chain Management (GSCM) towards sustainability taking into account the automobile industry of India. It is observed that there is potential for future research in strategic issues and general sustainable development studies in SSCM. There is a need for growth in SSCM-based studies because they demand the involvement of more stakeholders to take into account all three dimensions of sustainability while they adopt business decisions along the supply chain. Sustainable supply chain management (SSCM) practices using SEM for understanding the causality among the TBL dimensions for Indian automobile industry.

Abstract: Supplier Relationship Management (SRM), is strategic planning and managing of all interactions with suppliers to maximize its value. Its application varies from construction industries to healthcare system and investment banks to aviation industries. Several buyer-supplier relationship models, as well as supplier selection and evaluation strategies, have been documented by many academicians and researchers. In this paper, through a comprehensive literature review of over 30 published papers, different theoretical models, empirical data and conclusions were analysed relating to SRM to find its role in establishing better supplier relationships. These journal articles were searched by using the keyword “supplier relationship management,” in databases of Mendeley Library, ProQuest, EBSCO and Google Scholar. This paper reviews the academic literature on different relationship models, supplier evaluation, and selection strategies to discuss its implications in different situations. It also describes the dominant factors responsible for buyer-supplier relationships such trust and power. Finally, conclusions have been drawn which can be validated by various researchers and can help practitioners in industries.

Keywords: Supplier Relationship Management, Supplier Performance, Supplier Selection

1. INTRODUCTION

In recent years, the management of strategic relationships between buyer-supplier has received increasing interest. Supplier relationship management (SRM) as defined by (Akamp and Müller, 2013) is the practice of planning, implementing, developing and monitoring company relationship with the current and potential supplier. Main management activities of supplier management are supplier selection and evaluation, supplier monitoring, supplier development and supplier integration. Supplier selection is regarded as the cornerstone of successful purchasing and supply management to maintain and enhance the competitive edge (Abdollahi et al., 2015). Articles on Supplier selection show quality as most popular factor followed by delivery, price, manufacturing capability, service, management, research and development, finance, flexibility, reputation, relationship, risk, and safety and environment (Thakur and Anbanandam, 2015).

Moeller et al., (2006) described the benefits of SRM Base as 1) Better Supplier Base, 2) Cope with significant problems easily, 3) Act better coordinated and more consistent, and 4) Enhance value creation for customers. Therefore, SRM is a comprehensive approach which enhances cooperation (business relationship level), coordination (process level), and communication (information systems level) between the company and its suppliers to continuously increase efficiency and efficacy of collaboration and concurrently enhance quality, security, and innovation (Mettler and Rohner, 2009).

This paper is organized in the following manner. The next section discusses the methodology used to identify, choose and analyse existing research studies on supplier relationship management and supplier selection strategies.

The analysis revealed dominant themes in the research on SRM and its relationship with supplier selection which are presented in the subsequent section. While a majority of research studies have attempted to inspect the buyer-supplier relationship, some have also examined the factors that affect the supplier relationship management systems. The paper presents some such challenges and future research directions that are discussed in the literature. The last section details conclusion of this study.

2. METHODOLOGY

Using the keyword “supplier relationship management” and “supplier selection,” journal articles were searched for journal articles in Mendeley Library, ProQuest, EBSCO and Google Scholar. The keyword was found either in the title or the abstracts of the paper. In Google Scholar, top hundred results were considered. The search on Google scholar was limited to the abstract and the title of the respective document. The articles found in searches was scrutinized by the list of articles in ABDC Journals and Schimago Journals. Over 30 articles were identified published between 2000 and 2016. The findings are presented below from the analysis of the papers reviewed. The authors combine several categories that were used to analyse the articles as given below.

Preliminary Analysis

Authorship: Most of the articles reviewed had multiple authors and the average lies between two and three. From the 30 papers reviewed, each paper has around 40 references. It adds up to more than 1200 references in total. About 50% of the articles reviewed are published in 2012 or later. Less than five articles are published before 2007.

Nature of Study: About 50% of the papers reviewed had a specific country context such as India, China, Switzerland, USA, Japan, United Kingdom, Netherlands, Finland, and Malaysia. Most of the papers were descriptive, a few were diagnostic or experimental, and others were case studies. The majority of papers used literature reviews to generate hypothesis and the conducted surveys and interviews to verify them.

Theories Utilised: Few research studies mentioned the theories which they applied in the context of supplier relationship management to generate the hypothesis. Some of these are Social Exchange Theory (SET), Grey Theory, Evolutionary Game Theory (EGT), Intellectual Capital (IC) Theories, Resource Dependence Theory (RDT), Transaction cost analysis (TCA), and Game Theory.

Research Methodologies Used: Different studies were classified according to the dominant research method and data sources such as secondary data, survey, case study or a combination of these. About ten articles were conceptual or theory development papers based on literature reviews; about six papers were based on primary case studies; another five studies were based on experimentally collecting data through questionnaires and then analyzing the data.

3. DOMINANT THEMES

One of the critical objectives of a systematic review of literature is to assimilate the key findings of the different studies and identify common themes of research. The purpose of this study is to consolidate perspectives on supplier relationship management and supplier selection. In-depth and iterative analysis of the papers helped us evolve four dominant themes namely, buyer-supplier relationships, supplier selection strategies, supplier evaluation strategies and supplier development strategy. The chosen topics reflect both quantitative and qualitative emphasis of the papers reviewed rather than a complete mapping of all possible variables of interest. The items relate to issues and factors which are associated with SRM presented as higher-order constructs operationalized through lower-level elements. We introduce two of the themes i.e. buyer supplier relationships and supplier selection in this paper, categorize the research studies reviewed under each one and present brief summaries of the studies. Given the space constraints, the studies presented

are reflective of the themes, although not purely representative.

3.1 Buyer-Supplier Relationship

In their contribution, (Wieteska Grażyna, 2016) described how companies should develop relationships with suppliers while facing high market volatility. It focused on flexibility and adaptability in the context of Supplier Relationship Management (SRM). Flexibility in supply chain results in effective response to the changes in supply, demand, and products. Adaptability is built up in the context of adjusting to significant environmental changes. Flexibility in relations can be achieved through Flexible Purchasing and Supplier Flexibility.

To identify the possible obstacles to the SRM integration is the central theme of (Oghazi et al., 2016), and he strives to provides solution suggestions to overcome these barriers. In this regard, the survey of the literature and subsequent analyses of the empirical findings represent that the SRM process integration can take place by the integration of its different sub-processes into strategic and operational characteristics. Strategic sub-processes describe the definition and the structure of the entire process whereas operational sub-processes refer to the executive phase of the process. In this context, the lack of goal congruence, commitment, and trust among the manufacturer and its supplier are the main potential barriers to the SRM integration.

According to (Soh et al., 2016), the seven dimensions that are commonly used in literature to denote buyer-supplier relationships (BSRs) are trust, involvement, business understanding, communication, commitment, information sharing and knowledge. Trust most is essential in BSR. Factors that affect trust: commitments, communication effectiveness, cooperation, and transparency. The findings reveal Supplier Quality (SQ) and Supplier Commitment (SC) have direct significant relationships with Supplier Performance (SP). It also reveals that no mediating effects of BSR upon the relationships between Supplier Engagement (SE) and Supplier Infrastructure (SI) to Supplier Performance (SP).

Ji et al., (2015) studied the changing of cooperation tendency among multi-stakeholders (buyers and suppliers). The Evolutionary Game Theory (EGT) is adopted to describe the phase of further evaluation by analysing green costs and its benefits to players. Results implied that recycling capability is a crucial factor for the cooperation tendency among multi-stakeholders in the long-run. Green purchasing relationships among multi-stakeholders will influence the payoffs of the suppliers and manufacturers (buyers) in a two-tier supply chain.

In the following article, (Anni-Kaisa Kähkönen et al., 2015) empirically examine the relationships between value-

creating activities and buyer's dependence, and to determine what kind of supplier relationship management activities might decrease or increase the dependence. The results of the study indicate that the value-creating activities of inter-firm learning and early supplier involvement in buyer-supplier relationships improve the buyer's dependence on its suppliers, whereas a supplier orientation does not. From this study, it could be implied that the firms should weigh the pros (value creation) and cons (dependence) and develop management practices and relationship strategies based on those.

Identification of four main categories of both buyer and supplier attractiveness plays an important role in the article of (Tanskanen and Aminoff, 2015). These are: 1) economic-based, 2) behaviour-based, 3) resource-based, and 4) bridging-based attractiveness. They found economic- and behaviour-based attractiveness present in all dyads, while resource- and bridging-based attractiveness are emphasized when the strategic intention has more explorative elements and when the aim is to leverage the dyadic relationship in developing businesses outside the dyad.

Exploring the key supplier management (KSM) phenomenon (Ivens et al., 2013) discusses: how should it be organized, what are the (organizational) implications, and which benefits can be realized? KSM deals with the question how to analyse, plan, manage, and control interactions with these key suppliers.

Rezaei and Ortt, (2013) designed a rule-based approach to segment the suppliers of a firm based on two overarching dimensions that capture these available segmentation criteria. Another methodological contribution of the paper is to develop and apply a general sensitivity analysis procedure for fuzzy rule-based systems. This analysis is used to identify the most crucial supplier capabilities and willingness criteria and to formulate better supplier development strategies. A fuzzy rule-based system is formed of four functional blocks: knowledge base, decision-making unit, fuzzification interface, and defuzzification interface.

Main focus of (Jeong et al., 2013) in their article is on SCM in manufactured housing (MH) industry and an SRM Framework called MSROM is developed. Critical issues identified in SCM are Variable supplier Lead time and consistent safety stock level and a poor supplier evaluation process these issues are solved by MSROM framework and others specific Optimisation model. Framework for MSROM has to main subsystems: Material Sourcing process and Material control process. Results showed that the proposed system was more effective in controlling supplier lead time.

Akamp and Müller, (2013) investigates which measures of supplier management could advance supplier performance and buyer satisfaction. They proposed a structural equation model which was analysed using Partial Least Squares (PLS). The conceptual model takes supplier selection and evaluation, supplier monitoring, supplier development, and supplier integration as independent variables while supplier performance and buyer satisfaction being dependent variables. The results show that mainly cooperative activities such as supplier development and supplier integration are effective while, supplier monitoring does not seem to have a positive influence on supplier performance.

Bemelmans et al., (2012) shed light on obstacles to, and opportunities for, increasing the effectiveness of construction firms in managing buyer-supplier relationships. More specifically, the focus was on assessing the maturity level of buyer-supplier relationship management by construction firms. Aspects important in determining the effectiveness of buyer-supplier relationship management for a buying company includes optimizing supply base in terms of both the number and the quality of its suppliers, attention towards managing a buying company's portfolio of suppliers, deciding to what extent suppliers have to be integrated into their own processes, and attention to developing suppliers, on the basis of an ongoing monitoring of their performance. The impeding factors can be summarized as the lack of formalization, documentation, and communication (both internally and with suppliers) linked to the various policies, plans, processes and measurement systems that form part of the management of buyer-supplier relationships.

In the following paper, (Liu et al., 2010) developed a 2X2 relationship quality (RQ) matrix based on levels of mutual trust and commitment between both buyers and suppliers and explore the use of control mechanism. The research also tests the matrix and hypothesis proposed using the cluster, ANCOVA and SEM analysis. Based on the matrix different levels of trust and commitment can be developed namely the buddy, relier, arm's-length and initiative.

Svante Andersson and Per Servais, (2010) reviewed international industrial purchasing and marketing literature on portfolio models, to develop portfolio models for buyers' and sellers' international strategies, and to consolidate the models so that both the buyer and seller perspectives are dealt with simultaneously. He stated five product-related basic dimensions for buying situations: (importance, complexity, familiarity, innovativeness, and frequency) and three buyer-seller interaction-related dimensions (familiarity, dependence, and depth of interaction). These dimensions are used to develop a portfolio model of supplier relationship management and a marketing management model for supplier strategies. This study also examines how the different marketing management strategies fit with different supply strategies

and buying situations. The author concluded that to find a fit between buyers' and sellers' international strategies, the parties have to negotiate.

In this article, (Griffith and Lusch, 2008) determined how the individual elements of procedural justice influence the long-term orientation of a channel partner. Procedural justice refers to the perceived equity in the policies and procedures used within the relationship for resolving disputes and allocating outcomes. From the analysis it is implied that more open communication (bilateral communication, explanation) may not increase long-term orientation if the channel relationship doesn't become more reliable (i.e., improved consistency and credibility) and/or unless treatment of channel partners (interactional norms) is enhanced, and/ or develop policies that integrate the interests of their channel partner (voice).

Ounnar et al., (2007) contributed to the improvement of customer-supplier relationship is a decentralized self-organized control model based on the concept of Holon. Holon is the decision-making centre linked with the production system of the entity such as 'product', 'resource', 'order' and 'staff' (PROSA). In this model, the decision system controls a group of actors' operations who are in a partnership. In this paper, in particular, Analytic Hierarchy Process (AHP) for the evaluation of the suppliers' network is discussed. It allows a supplier to become an intelligent production unit able to operate in self-organization with other companies.

Aim of (Moeller et al., 2006) is at the development of a Framework for Supplier Relationship Management. For this purpose, they adapted and applied insights from Customer Relationship Management (CRM) as well as existing findings in supplier management literature. According to them, SRM can be subdivided into the following three main and sequential phases: Out-Supplier Management, In-Supplier Management, and In-Supplier Dissolution Management.

In their contribution, (Hwan-Yann Su et al., 2013) explores how partnerships can be enhanced through making transparent Intellectual Capital (IC) information to partners in the supply chain setting. IC refers to the sum of all intangible knowledge resources – the sum of all individual and organisational knowledge and capabilities – a firm can utilize for competitive advantage. Providing information comprising two components of IC transparency – the transparency of essential business characteristics and the transparency of relationship atmosphere – produces higher supply chain partner trust, satisfaction, and commitment than not providing that information.

Jiang et al., (2011) seeks to present empirical evidence about the effects of trust and dependence in business relationships in the construction industry. They test the

extent to which trust and dependence act as antecedents to four dimensions identified from the literature as being important determinants of relationship quality: commitment, communication, satisfaction, and long-term orientation. Main conclusion that one gets from this research is that Trust has more significant impact on relationship consequences (commitment, communication, satisfaction and long-term orientation) than dependence.

Identification of criteria for achieving efficient contractor-supplier relations for long-term relationships with suppliers and continuous cost-reductions play a crucial role in the article of (Mikael Frödell, 2011). These criterions can be divided into four groups: attributes of the relationship, communication behaviour, conflict resolution, and commodity/supplier selection process formalization. This study found that the most eminent enablers are total cost focus, aligned core values as well as the willingness and capability for collaboration and development.

Petersen et al., (2008) used resource dependency theory (RDT) to examine the circumstance in which a supplier has increasing levels of power above the buyer, such that the supplier may have little motivation to yield control or withhold the exercise of this potential power. Managerial strategies are also explored that a buyer may implement to mitigate the influence of supplier power on the creation of relational capital within the relationship. The results of the study imply that dependency, socialization processes, supplier integration, and relational capital have a more complicated set of interrelationships that form a vibrant and dynamic context for the study of buyer-supplier relationships.

Giving an overview of opportunism (Hawkins et al., 2008) described two critical theories of opportunism namely Transaction cost analysis (TCA) and Social exchange theory (SET). Opportunism is an aggressive selfishness that disregards the impact of the firm's action on others example stealing, cheating, etc. Antecedents and consequences are also discussed with proposed paths for further research. Opportunism in procurement exchanges for services will be lower when contractual and relational governance is implemented.

Huang et al., (2011) examines the influence of guanxi (i.e., interpersonal social ties) between supplier salespersons and retail buyers in the retail industry in China. Applying a mixed-method study combining both qualitative and quantitative stages, they found that guanxi between supplier salespersons and retail buyers may not improve retailer-supplier relationship quality. Furthermore, their results show that guanxi between supplier salespersons and retail buyers may decrease the positive effect of supplier role performance on retailer satisfaction.

Identification and analysis factors that inhibit or facilitate the sourcing processes with indigenous Chinese firms is the central theme of (Giannakis et al., 2012), and it explores the effect of distinct Chinese cultural characteristics on the nature of supplier relationship management. Factors that promote or inhibit supplier relationships' management: sourcing processes, governance structure, interaction process and multiple regression. The research also shows that guanxi has significantly positive relationship with suppliers' satisfaction with the supplier relationships.

3.2 Supplier Selection Strategies

Based on our investigation, we summarize five strategies that had been used for supplier evaluation and selection. Readers can find the typical usage of these techniques in the corresponding articles.

In the following article, (Thakur and Anbanandam, 2015) proposed a Multi-Attribute Decision Making (MADM) model based on the grey theory for optimal supplier selection in the context of Indian banking industry. This optimal selection helps a lot to provide the best supplier for "optimizing digital banking" services under uncertainty. Grey theory includes five significant parts: grey prediction; grey relational analysis; grey decision; grey programming; and grey.

In their paper, (Abdollahi et al., 2015) described a theoretical framework for supplier selection based on the two groups of "lean" and "agile" suppliers is presented and a guideline for supplier relationship management (SRM) for these suppliers has been proposed. To determine the precise interdependencies between the suggested criteria, fuzzy decision making trial and evaluation laboratory (DEMATEL) is applied to the problem. Moreover, Analytical network process (ANP) application finds the weight of each sub-criterion, and finally, Data envelopment analysis (DEA) approach is utilized to rank the suppliers regards to their score in each criterion.

Yeniyurt et al., (2013) found in their study that if a sourcing organization strives to achieve exceptional supplier working relations, it should be integrated across its geographic regions with knowledgeable global and local procurement personnel which effectively communicate with the company's suppliers, while working collectively in a coordinated manner to achieve a globally responsive supply chain.

Wu and Shen, (2006) developed a strategy-based planning process to guide user requirements determination. It focuses on problem structuring issues; i.e., the unstructured problems of the SRM domain. An analysis of buyer-supplier behaviour in developing a relationship with suppliers. The planning process includes three steps: define purchasing strategies, identify supplier selection criteria, and determine system requirements. Olsen and Ellram

model which includes four situations (namely Bottleneck, Strategic, Non-critical and Leverage) has more power in interpreting research findings. So it was chosen for the survey. This new approach fundamentally overcomes the impact of problem unstructured issues associated with SRM domain toward user requirements determination of e- SRM.

According to (Choy et al., 2003, 2004), there is an urgent need for developing an enterprise application integration (EAI) system for outsourced type manufacturers so that selection of appropriate suppliers can be made through a common Web-based platform. By doing so, customers' need can be directly related to suppliers' capability. This paper focuses on the integration of the Customer Relationship Management (CRM) and Supplier Relationship Management (SRM). By developing an Intelligent Supplier Relationship Management System (ISRMS) using Case-Based Reasoning, the author is making a system for potential supplier selection, and it is tested in Honeywell Consumer Products Limited. Case-Based Reasoning (CBR) is a method for solving Problems using previous similar situations from the case Database. Its Process uses 4 "Re's": Reuse, Retrieve, Revise and Retain. Its applications can be classified into two types- Classification Tasks and Synthesis Tasks. CBR can be applied in Planning, Design, Diagnosis of Diseases and customer service section. In ISRMS two CBR modules are present, Supplier selection and Help Desks.

4. THE CHALLENGES AND FUTURE RESEARCH DIRECTIONS

Research of (Oghazi et al., 2016) stated ten obstacles that can slow down and prevent the integration of SRM from occurring. These are the lack of trust, lack of communication and shared goals, lack of standard tools, lack of commitment, lack of willingness, specificities of the IT system, degree of formality, security barriers, inflexibility, and cost of integration.

Based on the systematic review we found the following directions for future researchers:

- Supplier development programs aimed at improving the flexibility of suppliers' production systems (WieteskaGrażyna, 2016).
- Use of grey theory for multiple-supplier selection in the manufacturing sector where one cannot always rely on a single supplier (Thakur and Anbanandam, 2015).
- Anni-KaisaKähkönen et al., (2015) suggested:
 - Examination of the effects of early supplier involvement, inter-firm learning and a supplier orientation on supply performance and company innovativeness.

- Identification the other value-creating components in business relationships, and control the firm-specific effects such as the duration of the relationship and the asymmetric sizes of business partners.
- An in-depth investigation into the association between dependence and relationship risk.
- Constraints related to establishing and maintaining contractor-supplier relationships within the construction industry (Mikael Frödell, 2011).
- Determination of optimum portfolio of relationship types between contractors and suppliers in the construction industry (Bemelmans et al., 2012).
- Examining whether the individual elements of procedural justice differ in importance over the duration of the relationship development process (Griffith and Lusch, 2008).
- Building a more precise conceptualization of key supplier relationships (KSM), and sharpening and deepening the link between KSM and other streams of literature, specifically for strategic management (Ivens et al., 2013).
- Influence of stakeholders (like local government, etc.) in Green Purchasing (Ji et al., 2015).

5. CONCLUSION

This paper provides a systematic literature review of articles published from 2000 to 2016 on the supplier relationship management and selection strategies. It aims to analyse the collected articles from two analytical aspects: buyer-supplier relationships and supplier selection. A total of 30 journal articles were carefully selected and reviewed in detail. We systematically summarized the SRM models and supplier evaluation techniques. This paper provides valuable knowledge accumulation about current studies and directions for future works.

This study has two major limitations. First, our review focuses on the application SRM and supplier selection. Other important aspects such as supplier development, were not involved in this review because of the limited research scope. Second, the reviewed articles were published from 2000 to 2016 and searched based on the keywords “supplier relationship management,” “supplier selection,” and “SRM.” Some articles published in late 2016, if any, may not be included in this review because of the limitation of reporting time. A future study could be expanded in scope.

Criteria for Supplier Selection and Supplier Evaluation: A Literature Review

Manoj Kumar Dalvi¹, Ravi Kant²

¹ Department of Mechanical Engineering
Bhivrabai Sawant College of Engineering, Pune, Maharashtra, India.

² Department of Mechanical Engineering
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

Abstract: Supplier selection (SS) is currently a subject of great importance to organizations. SS and supplier evaluation (SE) is a multi-criterion decision making problem which includes both qualitative and quantitative criteria. These criteria affect on evaluation of performance of suppliers and decision-making process. In order to select the best suppliers it is necessary to make a trade-off between these tangible and intangible criteria some of which may conflict. This paper reviews the literature of SS and SE and the performance criteria from 1966 to till date related articles appearing in the international journals are collected and studied to answer the above mentioned questions or to accomplish the objectives of this paper. This paper identifies some of the important criteria of SS and SE. This paper also attempts to find few criteria as per their level of importance based on the occurrence listing and which evaluation criteria were paid more attentions?. These important criteria for SS and SE are namely cost, quality, performance etc.

Keywords: Supplier selection, SE, vendor selection, vendor evaluation, performance criteria.

1. INTRODUCTION

In today's competitive operating environment it is impossible to produce or assemble the products at lower cost with high quality without suitable suppliers. Thus, one of the most significant purchasing decisions is the selection and maintenance of a capable group of suppliers (Weber et al., 1991). Supplier selection and SE is the process of finding the suitable suppliers those are capable of supplying the buyer with the right quality products and/or services at the right price, in the right quantities and at the right time (Zhang et al. 2009). The environment for taking decision about suppliers and their capability to deliver the products is a complex activity, as it includes high levels of ambiguity and uncertainty, competing stakeholder values and complicated relationships as a result of multiple conflicting objectives (Watt et al. 2009). Organizations revealed that suppliers offering lower prices did not necessarily provide best quality or service performance. They also pointed out that SE can be a multi-objective decision of lowest cost, best quality and service performance (Che and Yang, 2007). Still the organizations have to make tradeoffs between these criteria. To select the appropriate suppliers, two aspects including importance degree of the selection criteria, and suppliers' performance with respect to these criteria are essential (Ordoobadi, 2009). SS and SE is considered to be much important because criteria used in the evaluation process depend from industry to industry as per the level of importance, therefore this paper contains the opinion of different authors about the level of importance for criteria of supplier selection. SS and SE is a typical multiple criteria

decision making problem that involves multiple criteria like qualitative and quantitative. So it becomes apparent that the supplier selection process should include a suitable number of criteria, based on which, the organizations would be able to select the most appropriate supplier for the product/assembly under consideration. Also there is no previous exclusive literature survey is available on SS and SE criteria. This paper attempts to identify the number of criteria of SS and SE through the literature review.

In this paper, we thoroughly collected the literature related with the keywords "supplier selection", "SE", "vendor selection", "vendor evaluation", "performance criteria" from academic databases including Science Direct, Emerald, Springer-Link Journals, IEEE Xplore. As per the span and keywords from academic databases we collected and reviewed 94 international journal articles published from 1966 to till date. This paper attempts to identify the various criteria of SS and SE, also to find the few key criteria as per the level of importance. The remainder of this paper is organized as follows: Section 2 presents detailed literature review of SS and SE criteria. This paper is concluded in including the suggestions for future works.

2. LITERATURE REVIEW

This paper reviewed the journal articles those are published in the academic databases i.e. Sciondirect, Emerald, Taylor & Francis and Springer. More than 94 papers were reviewed to achieve the above mentioned objective of this paper. Only articles that had been published on SS and SE, performance criteria for SS/SE. These articles were

collected from academic databases including Science Direct, Emerald, Taylor & Francis Journals and Springer. “Supplier selection,” “vendor selection,” “supplier evaluation,” “vendor Evaluation,” “performance criteria” used as keywords for search and the literatures that has been published till date were accepted. Conference articles,

master and doctoral dissertations, text books, unpublished articles and notes were keep out of this research only the related articles in international journals were accepted for review. Based on this research methodology 30 important SS/ SE criteria were finalized which are as follows

TABLE 1.1: Criteria and Representing Literatures

Criteria	Representing Literatures
Cost	Youssef et al, (1996), Sevkli et al., (2003), Dickson et al, (1978) O’Shaughnessy (1974), Wilson (1994), Dahel (2003), Dickson (1966), Choy & Hartley (1996), Verma & Pullman (1998), Krause et al, (2000), Tracey & Tan (2001), Wang et al, (2010), Cardozo & Cagley (1971)

3. CONCLUSION

SS is a crucial decision making problem which involves both qualitative and quantitative evaluation of multiple criteria under consideration. This paper summarizes the important criteria for SS. The role of SS process recently an important concern for industries since it reduces cost which leads to increase the profit and competitive advantage. However, there are many criteria that companies can decide and this makes it difficult to decide the importance of criteria for taking decision. This research is done in two phases. In first phase this literature review represents various important criteria for SS.

The second phase attempted to determine few important criteria based on occurrence listing, with some concluding remark. This literature review provides valuable information, knowledge and current studies about the criteria of SS and SE. This literature review attempts to provide an overview of the body of the 94 papers having SS and SE criteria, which are published in the academic databases Sciencedirect, Emerald and Taylor & Francis and Springer. After analysing the data it shows that most of the

researchers have worked on the MCDM techniques for SS/SE. No exclusive or extensive survey has been conducted for identifying the criteria of SS/SE with their level of importance.

This review illustrated that in early phase cost was the single criteria for taking decision about the SS. After this criteria like quality, on time delivery and service were gaining most of the importance for taking decision. Now a day along with these above mentioned criteria, it is required to focus on environmental performance of supplier. This paper also identified the important criteria based on the occurrence listing like cost, quality on time delivery, flexibility, production facilities, technical capability and performance in industry etc. Environmental performance, social performance and geographical location of supplier needs to be taken care with the important criteria like quality, on time delivery, service, cost etc. As a part of future scope, there is a need of identifying the importance of these criteria through the expert survey by industry experts or field practitioners for different sectors and types of industry.

Humanitarian Supply Chain Management: An Overview

Sachin Agarwal, Ravi Kant

Department of Mechanical Engineering
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

Abstract: The purpose of this paper is to present a brief overview of the field of humanitarian supply chain management (HSCM). HSC is activated instantly after the happening of a disaster, with the intend of saving lives, alleviating suffering of the victims, and reducing the impact on the constancy of the society. The unpredictability of global emergency disaster and the risk of the plenty and timely delivery of the goods/services is the challenge in the relief operations. This paper presented HSC involvement in four phases of a disaster life cycle. HSC must focus to supply an appropriate level of resources, materials to disaster affected locations globally in order to curtail human suffering and loss of life. The paper also detailed role and responsibilities of different stakeholders in HSC.

Keywords: Humanitarian Supply Chain, Humanitarian Logistics, Logistics Providers, Disaster.

1. INTRODUCTION

The procurement, warehousing, transportation activities and infrastructure that are associated with acquiring and distributing relief materials are the primary components of a relief effort, with logistics making up 80 percent of humanitarian operations (Van Wassenhove, 2006). HSCM is the process of, implementing, planning and controlling the proficient, cost-effective flow and storage of goods and materials, as well as related information, from the point of source to the point of utilization for the intention of

alleviating the suffering of affected people. The task includes a range of activities, including transport, preparedness, planning, warehousing, procurement, tracking and tracing, and customs clearance (Thomas and Kopczak, 2005). The HSC (Humanitarian Supply Chain), unlike the CSC (Commercial Supply Chain) does not have the usual supply chain stages like those of suppliers, manufacturers, distributors, retailers and customers. Instead, the humanitarian supply chain consists of donors, international agencies, International NGOs, local bodies and the consumers (Oloruntoba and Gray, 2006)

Fig. 1. A typical HSC, Source: Oloruntoba and Gray (2006)

Beamon (2004), Thomas and Kopczak (2005), and Van Wassenhove (2006) illustrate the unique character of the disaster relief atmosphere and evaluate humanitarian supply chains with the commercial supply chains. There are basic differences between commercial supply chains and HSC in terms of their, consumer and demand distinctiveness, strategic goals and environmental factors. The governing characteristics that bring additional complexity and unique challenges to HSC design are:

- i) Be short of of goods (supply, people, technology, transportation capacity, and money)
- ii) Suddenly uncertain demand occur in very large amounts and short lead times for a wide variety of supplies,
- iii) High stakes associated with adequate and timely delivery,

- iv) Unpredictability of demand, in terms of timing, location, type, and size,

2. DISASTER CLASSIFICATION

Natural Disaster Classification (Guha-Sapir, Annual Disaster Statistical Review 2015) as shown in the table No. 1 with the number of disasters occur in the year 2015. In the year 2015, natural disasters once again had a devastating impact on human society. Total 376 natural disasters occurred in the ear 2015 (330 disaster occur in the year 2014 (rise of 14%)) caused the death of 22, 765 people (2014's 7, 959). Disaster affected 110.3 million victims and caused US\$ 70.3 billion damages. The five most frequently disaster affected countries were China (36), USA (28), India (21), Philippines (15) and Indonesia (10), which results 30 % of total disasters occurs in 2015. Floods remain the most frequent natural disaster in 2015 in the world.

TABLE1: Natural Disaster Classification

Geophysical (29)	Hydrological (175)	Meteorological (127)	Climatological (45)	Biological	Extra Terrestrial
•Earthquake (21) •Volcanic activity (7)	•Flood (156) •Landslide •Wave action	•Storm (115) •Extreme temperature (12) •Fog	•Drought (34) •Wildfire (11) •Glacial Lake outburst	•Epidemics •Insect Infestation	•Space weather

TABLE 2: Categorizing Disasters, Source: Van Wassenhove (2006)

Disaster type ↓ →	Natural disaster	Man-made disaster
Sudden on set disaster	Earthquake, Hurricane, Tornado, Tsunami	Chemical leaks, Terrorist attack
Slow on set disaster	Famine, Draught,	Political crisis, Refugees crisis

3. DISASTER LIFE CYCLE

There is rise in natural and man-made disasters and the victims affected by them have also increased in last few years. In the last decades, the area of disaster management and HSCM has gained significantly attention, and there are a number of literature review article in these area. Altay and Green (2006) have distinct four phases of a disaster life cycle: mitigation, preparedness, response, and recovery.

Mitigation: The mitigation phase is related to actions to reduce or diminish the potential impact of disasters. Preventing future occurrence, emergencies or minimizing their effects. Includes any activities that avoid an emergency, reduce the chance of an emergency happening, or reduce the damaging effects of unavoidable emergencies. This phase includes activities that avoid a disaster emergency, reduce the likelihood of occurrence of a disaster, or reduce the damaging effects of inevitable hazards. Mitigation activities should be considered long ahead of an emergency.

Preparedness: The preparedness stage is related to activities carried out before a disaster in preparation for the suitable responses. Preparing to handle an emergency. Includes plans or preparations made to save lives, rescue operations and to help response. Preparedness phase takes place before an emergency happens. This phase comprises developing plans for what to do, who to call, or where to go for help before an event occurs; actions that will recover your chances of successfully dealing with a crisis.

Response: Response is putting the preparedness plans into action. Response activities take place during an emergency. The main aim of a disaster response phase is rapid relief action (supplying emergency food, water, medicine, shelter, etc.) in the disaster affected areas, to minimize suffering,

losses and death. To safely response a disaster operation in an emergency condition is the major challenge. It comprises actions taken to save lives and avoid further property damage in an emergency situation.

Recovery: The recovery phase usually involves long-term activities to recover the losses occurs due to disaster. It consists of actions taken to return to a normal or an even safer situation following an emergency. Recovery activities take place after a disaster occurs.

Fig. 2. Disaster Life Cycle, Source: Altay and Green (2006)

4. STAKEHOLDERS IN HSCM

Humanitarian logistics (HL) involve different parties, including governments, military, non-governmental organizations and aid agencies that differ widely in structure, size, aims, and knowledge (Van Wassenhove, 2006; Argollo da Costa et al., 2012). When major natural or man made disasters strike, international non-governmental organizations (NGOs), UN agencies, intergovernmental humanitarian organizations (HOs), national societies, governmental organizations, military institutions, and many others logistic service provider's move quickly to provide relief. United Nations bodies, local and international non-governmental organizations (NGOs) and host governments, as well as donors, military and logistics service providers are all concerned in one form or another. A number of the

operative bodies tend to specialize in rescue operation like camp management, medical care or food, water and sanitation (Jahre and Spens, 2007).

In humanitarian supply chains (HSC) donors and beneficiaries are both customers (Oloruntoba and Gray, 2009; Charles et al., 2010). HSC is a more complex structure than in a commercial supply chain, where suppliers are being paid and customers pay for the goods and services they receive. Performance measurement in particular becomes difficult, as various stakeholder groups measured performance in different ways. Table 3 detail roles and responsibilities of stakeholders. There is a lack of coordination in disaster relief logistics and HSC where combined actions among different international organizations are required (Kovacs et al., 2010).

TABLE 3: Roles and responsibilities of stakeholders

S. No.	Stakeholders	Roles/ Responsibilities
1	NGO's	To give the supports to humanitarian operation based on its role. NGO gave financial humanitarian aid in cash as well as in material form to support the operation, it collect the financial from consumers, employee and provider to support the operation.
2	Government	It mobilizes resources and they the power to authorize humanitarian operations in disaster affected regions.
3	Donor's	Donors give financial support to fund in humanitarian aid operations.
4	Military	A very significant player since soldiers are called upon to offer primary assistance, for example: food supply, hospital and camp installation.
5	Logistics provider	It assists HSC during disaster.
6	Aid agencies	Agencies to fund relief operations.

Fig. 3. Actors of supply network of humanitarian aid,
Source: Kovács and Spens (2007)

5. COMMERCIAL AND HSC

There are important differences between commercial supply chain and humanitarian supply chain (Oloruntoba and Gray 2006). The commercial supply chain is fairly stable as compared to HSC. Commercial supply chain has the benefit of precedent demand to forecast future demand. This means that commercial supply chain operates in a predictable environment, while humanitarian supply chain work in highly unpredictable environment. Table 4 list the difference between commercial supply chain and humanitarian supply chain.

TABLE 4: Difference between Commercial SC and HSC

Characteristic	Commercial supply chain	Humanitarian supply chain
Supply/Supplier	• Determined suppliers. • Supplier know the consumer	• It is difficult to select particular supplier. • Demand vary

Characteristic	Commercial supply chain	Humanitarian supply chain
	demand. • Systematic collection and performance monitoring	during the response phase of disaster.
Organization involved	• Well join with each other. • Having long-term relationship	• Unknown and voluntary partnership. • Relationship develops during the relief operations.
Demand/ Requirement	• Stable demand. • Precedent data can be used to predict the order.	• Mostly unstable demand. • Extremely unstable demand with time • Need quick assessment and information. • No generalized technique available
Network design	• Moderately stable	• Uncertain and unstable

6. CONCLUSION

After the Tsunami in 2004, HSCM have received significant concentration from both the humanitarian practitioners and academicians. A typical HSC required support from the government, aid agencies individual donors, international aid agencies and non-governmental organizations (NGOs). This article detailed role and responsibilities of the various stakeholders that helps in a humanitarian operation to provide relief in disaster affected areas. Due to unpredictable demand, location and type of disaster, there is vast difference between commercial supply chain and humanitarian supply chain as discuss in the article.

Measuring Service Quality of Retail Outlets: An Empirical Investigation in Northern part of Tamil Nadu

Karuppuchamy P.

School of Retail Management,
Foot Wear Design & Development Institute, Chennai, Tamil Nadu, India

Abstract: This present work attempts to measure the service quality and its impact on customer's satisfaction in retail outlets of Chennai city. The instrument was designed to measure the perception of customers on the quality of service offered by retail outlets in Chennai. After a comprehensive review of literature and based on the brainstorming with experts in retail management and industry, an attempt has been made to conceptualize five quality constructs pertaining to service quality and develop an instrument, from the customers' perspective, in order to measure the service quality of retail outlet. The following are five dimensions under this model: (a) Infrastructure facilities (b) Management Responsibility (c) Employee and Customer Interaction (d) problem-solving, and (e) Business policy. This study has applied the stratified random sampling method to obtain the responses from shoppers of supermarkets in Northern part of Tamil Nadu, and it is disproportionately distributed. In the light of literature review, the retail service quality model is found to be the most suitable for measuring service quality. The results of the study show that the retail service quality has a positive correlation with customer satisfaction.

Keywords: Customer Satisfaction, Service Quality, Retail Service Quality Model, Retail Service Quality Scale

1. INTRODUCTION

For the past few years, retail sector has been experiencing the highest growth rate in terms of revenues in many countries as well as India. Retailing is the world largest private sector contributing to 8% of GDP and its employee one six of labor force. It contributes 10% of GDP and its second largest sector next to agriculture which provides maximum employment to the people. Today the quality of products and services consumed is of great importance. It is widely accepted that surviving in difficult and competitive conditions of a market economy requires good quality production. To understand and assess the results of efforts realized for good quality production, quality should be measurable..

2. MEASURES OF RETAIL SERVICE QUALITY

Service quality in retailing is different from any other product/service environment (Finn, 2004). Because of the unique nature of retail service, improvements and measurements of quality in retailing cannot be approached in the same way as that of the services perspective. In retail service, it is necessary to look at quality from the perspective of services as well as goods and derive a set of items that accurately measure this construct (Mehta *et al.*, 2000). For this reason, Dabholkar *et al.* (1996) developed and empirically validated the Retail Service Quality Scale (RSQS) to capture dimensions important to retail customers based on the triangulation qualitative research technique. They conducted qualitative research using three different methodologies - phenomenological interviews, exploratory depth interviews, and tracking the customer through the

store. Combining these qualitative findings with the existing literature and SERVQUAL, Dabholkar *et al.* (1996) proposed that retail service quality has a hierarchical factor structure comprising five basic dimensions, namely 'physical aspects', 'reliability', 'personal interaction', 'problem solving', and 'policy', with first three basic dimension having two sub-dimensions each and overall service quality as a second order factor. The sub-dimensions of the basic dimension 'Infrastructure' are: 'appearance' and 'Convenience'; the sub-dimensions of the basic dimension 'Management Responsibility' are: 'promises' and 'doing it right'; and the sub-dimensions of the basic dimension 'personal interaction' are: 'inspiring confidence' and 'courteousness/helpful'.

3. LITERATURE REVIEW

Parikh (2006) said that "As retailing develops in India, retail outlets in India will have to improve the quality of their services significantly in order to compete successfully in the global marketplace. It is, therefore very important to know how customers evaluate service quality and what can be done to measure and improve it. Azhagan & Nagarajan (2011) analyzed that "most of the customers prefer Retail sector because of more Tangibles and Empathy towards its customers. In order to retain and attract new customers, the organized retail sector should improve customer's service level and should provide assurance towards its customer." Singh (2013) stated that "In retail outlet service quality is having a significant influence on purchasing and repurchasing decisions, positive word of mouth as well as on complaining behavior in retailing". William & Prabakar

(2012) concluded that “The customer perception of retail service quality is an important segment to the emerging and the existing retailers in the market as the study reveals that perception of service quality influenced by the various nature with various customers even some of the general factors like Personal interaction, Infrastructure are the dimensions on of the customer perception remains constant and common to all the customer on a majority basis so the retail outlets have to frame their own strategies In order to attract the customers on a longer basis” .Kumar.R & Barani (2012) said that “service quality has long been accepted as the most basic marketing tool for retailers to differentiate their retail offers, create competitive advantage and to enhance the customers’ shopping experience. Nonetheless, maintaining excellent service quality within the stores is no simple task” U. Dineshkumar, P.Vikkraman (2012) found in their study that “ retail outlets provide better quality of service and most of the customers are satisfied with the quality of service provided by the retail outlets.” Kumar.R & Barani (2012a) identified in their study that “tangibles, reliability, responsiveness, competence, credibility, accessibility and customer knowledge are positively related to customer satisfaction. However, only four variables have significant effect on customer satisfaction.

4. OBJECTIVES OF THE STUDY

The main objective of the study is to find out the significant impact of retail service quality on customer satisfaction among retail outlets in Northern part of Tamil Nadu . Further, the secondary objectives are; to find out significant relationship between retail service quality and customer satisfaction; finally to suggest the retail outlets to frame the marketing strategies which will enhance the retail service quality and customer satisfaction.

5.1 Retail Service Quality and the Instrument

Dabholkar, Thorpe and Rentz (1996) proposed that retail service quality has a hierarchical factor structure. While different researchers think of retail service quality at different levels. Dabholkar, Thorpe and Rentz (1996) proposed five dimensions—physical aspects, reliability, personal interaction, problem solving, and policy. They also expanded sub-dimensions of each dimension to combine related attributes into sub-groups. The instrument was designed to measure the perception of customers on the quality of service offered by retail outlets in Chennai. After a comprehensive review of literature and based on the brainstorming with experts in retail management and industry, an attempt has been made to conceptualize five quality constructs pertaining to service quality and develop an instrument, from the customers' perspective, in order to measure the service quality of retail outlet. The following are five dimensions under this model: (a) Infrastructure facilities (b) Management Responsibility (c) Employee and Customer Interaction (d) problem-solving, and (e) Business

policy . They also expanded sub-dimensions of each dimension to combine related attributes into sub-groups. This study has applied the stratified random sampling method to obtain the responses from shoppers of supermarkets in Chennai city, and it is disproportionately distributed.

In the light of literature review, the retail service quality model is found to be the most suitable for measuring service quality. Five dimensions are defined as follows Infrastructure facilities :Physical facilities, equipment, and appearance personnel Management Responsibility: The ability to perform the promised service dependably and accurately Employee and Customer Interaction: retail store personnel are courteous, helpful, and inspire confidence Problem solving - retail store personnel are capable to handle returns and exchanges, customers’ problems and complaints.Policy - retail store’s policy on merchandise quality, parking, operation hours, and credit cards These five dimensions were expected to be distinct, but highly correlated. Three of the five basic dimensions of RSQS have two sub dimensions each. RSQS includes 27 items which of 17 items were extracted from SERVQUAL and 10 items developed from literature review and their qualitative research.

5.2. Hypotheses of the Study

The following hypotheses are formulated in this study:

H1: There is a significant impact of retail service quality on customer satisfaction

H1a: There is a significant impact of physical aspects in the retail service quality on customer satisfaction

H1b: There is a significant impact of reliability in the retail service quality on customer satisfaction

H1c: There is a significant impact of personal interaction in the retail service quality on customer satisfaction

H1d: There is a significant impact of problem solving in the retail service quality on customer satisfaction

H1e: There is a significant impact of policy in retail service quality on customer satisfaction

H2: There is a significant relationship between retail service quality and customer satisfaction

H1a: There is a significant relationship between Infrastructure in the retail service quality and customer satisfaction

H1b: There is a significant relationship between Management Responsibility in the retail service quality and customer satisfaction

H1c: There is a significant relationship between personal interactions in the retail service quality and customer satisfaction

H1d: There is a significant relationship between problem solving in the retail service quality and customer satisfaction

H1e: There is a significant relationship between policy in retail service quality and customer satisfaction

6 METHODOLOGY

6.1. Research Model

Quantitative study has been focused to answer the research question as what extent retail service quality influences on the customer satisfaction. In which, retail service quality is viewed as an independent variable and customer satisfaction is considered as the dependent variable.

$Y_i = \beta_0 + \beta_1 X_{1i} + \beta_2 X_{2i} + \beta_3 X_{3i} + \beta_4 X_{4i} + \beta_5 X_{5i} + \epsilon_i$
According to the above model, we can construct the new research model for the study.

$CS = \beta_0 + \beta_1 IF + \beta_2 MR + \beta_3 ECI + \beta_4 PS + \beta_5 PO + \epsilon_i$

Where:

CS = Dependent Variable (Customer Satisfaction)

β_0 = Intercept

β_1 = Population slope **β_2** = Population slope **β_3** = Population slope **β_4** = Population slope **β_5** = Population slope

IF = Independent variable (Infrastructure facilities) **MR** = Independent variable (Management Responsibility)

ECI = Independent variable (Employee- Customer Interaction) **PS** = Independent variable (Problem Solving)

PO = Independent variable (Policy) **ϵ_i** = Random Error

6.2. Study Design and Methods

6.2.1. Sample

The population of this study is the consumers of retail outlets in Chennai city. The most leading retail outlets were selected for the study and data were collected in Chennai city. Consumers of 16 Retail outlets were randomly selected to distribute the questionnaire. Systematic quasi-random

sampling method was used to select the sample of the study. This sampling method was chosen because it permits analysis of possible selection bias or error (Ndubisi, 2006). The data were collected on 12th of June 2017 from 10.00 a.m. to 4.00 p.m. The structured questionnaire was given to two consumers in every one hour who shopped at retail outlets and who confirmed their willingness to respond to the questionnaire. They were selected on the basis of systematic sampling technique.

6.2.2. Study Variables, Questionnaire Design and Data Collection

The RSQS questionnaire developed by Dabholkar, Thorpe and Rentz (2006) was used as the data collection instrument. The questionnaire has been slightly modified as it translated into Tamil to ensure suitability for the research context and it mainly consisted with three parts. Part A considers the respondent's personal profile and part B consists of 28 items relating to retail service quality in supermarkets and one item relating to overall customer satisfaction. One item was excluded from the original RSQS which consisted with 27 items. The fact was proved once the questionnaire was examined for the face validity by two academics who are experts in marketing and consultancy and four store managers from each of four brands of supermarket chains. Part C contained with two open ended questions, one was to know the leading reasons for consumers to retail outlet and the other one was to know consumers' suggestions to improve the retail service quality. A seven-point Likert scale from '1-strongly disagree' to '7-strongly agree' was used to measure the items. The questionnaires were distributed to 175 respondents from 16 outlet chains in Chennai. Out of 175, 160 completed questionnaires were selected for the final analysis after deleting 15 incomplete records with an effective response rate of 91.4% of the total sample.

6.2.3. The Reliability Statistics

To examine reliability of the scale dimensions, the Cronbach's Alpha was calculated, as it considered as the most widely accepted reliability measure. Table 2 provides the Cronbach's Alpha (α) for the five

Retail Service Quality Dimensions and Items Used in the Study with the Reliability Measures

Sl.No	Items	Dimension	Cronbach's Alpha
1	This store has modern-looking equipment and fixtures	Infrastructure facilities	0.764
2	The physical facilities at this store are visually appealing.		
3	Materials associated with this store's service (such as shopping bags, catalogs or statements) are visually appealing.		
4	This store has clean, attractive and convenient public areas		
	(restrooms, fitting rooms).		

Sl.No	Items	Dimension	Cronbach's Alpha
5	The store layout makes it easy for you to find what you need.	Management Responsibility	0.772
6	The store layout makes it easy for you to move around in the store.		
7	When this store promises to do something by a certain time,		
	it will do so.		
8	This store provides its services at the time it promises to do so		
9	This store performs the service right the first time		
10	This store has merchandises available when you want it.	Employee - Customer Interaction	0.746
11	This store insists on error-free sales transactions and records		
12	Employees in this store have the knowledge to answer your questions.		
13	The behavior of employees in this store instills confidence in you.		
14	You feel safe in their transactions with this store.		
15	Employees in this store give prompt service to you		
16	Employees in this store tell you exactly when services will be performed		
17	Employees in this store are never too busy to respond to your requests		
18	This store gives you individual attention.		
19	Employees in this store are consistently courteous with you		
20	Employees in this store treat you courteously on the telephone.		
21	This store willingly handles returns and exchanges	Problem solving	0.725
22	When you have a problem, this store shows a sincere interest in solving it.		
23	Employees of this store are able to handle your complaints directly and immediately		
24	This store offers high quality merchandise	Policy	0.739
25	This store provides plenty of convenient parking for customers		
26	This store has operating hours convenient to all their customers.		
27	This store accepts most major credit cards.		

7.1. Correlation Analysis

	Infrastructure facilities	Management Responsibility:	Employee - Customer Interaction	Problem solving	Policy	Retail Service Quality	Customer Satisfaction
Infrastructure facilities	1	0.494	0.600	0.621	0.510	.821	0.712
Management Responsibility		1	0.626	0.582	0.341	0.789	0.729
Employee and Customer Interaction			1	0.746	0.236	0.838	0.820
Problem solving				1	0.226	0.836	0.768
Policy					1	0.580	0.424
Retail Service Quality						1	0.894
Customer Satisfaction							1

Purpose of the correlation analysis is to find out the significant relationship between retail service quality and customer satisfaction. Further, it is utilized to find out the relationship between the dimensions or factors influencing on retail service quality as Infrastructure facilities, Management Responsibility, Employee-Customer Interaction, problem solving & policy and customer satisfaction. According to the analysis, retail service quality is positively associated with customer satisfaction, further,

strong positive association has been found, which is also in the significant level ($P < 0.05$). Meantime, all the dimensions which have been taken as the factors influencing on the retail service quality as Infrastructure facilities, Management Responsibility, Employee and Customer Interaction, problem solving & policy are also positively correlated. Except policy in the retail service quality, others factors have strong positive correlation with customer satisfaction

REGRESSION ANALYSIS

Variable	Beta Value	T- Value	P - Value	Adjusted R- Square	F- Value	Sig. Level
Constant		-2.234	.029	0.806	128.160	0.00
Infrastructure facilities	0.176	3.144	.002			
Management Responsibility	0.232	4.737	.000			
Employee- Customer Interaction	0.386	6.491	.000			
Problem solving	0.216	3.679	.000			
Policy	0.137	3.068	.000			

In this study, regression analysis has been utilized to find out the significant impact of retail service quality on customer satisfaction. Generally regression analysis is used to answer the question as what extent independent variables influence on the dependent variable. In this context, research question as what extent retail service quality influences on the customer satisfaction in the retail super markets is answered.

According to the analysis, 80 percent of the variation has been found which is in the significant level. It means that, customer satisfaction in the retail outlets is determined or influenced by the retail service quality. Further, customer satisfaction among retail super markets is also influenced by physical aspects, reliability, personal interactions, problem solving & policy in the retail service quality significantly.

8. CONCLUSIONS AND RECOMMENDATION

Retailer is an interface between upstream side and downstream customer of supply chain who insures the easy flow of goods to the customer. According to the results of the study, retail service quality in Chennai is positively associated with customer satisfaction. Further it revealed that all the dimensions have a strong positive correlation with customer satisfaction. It was also found that customer satisfaction among retail out is significantly influenced by the retail service quality. Policy in the retail service quality is measured by the measurements as high quality merchandise, convenient parking facilities, convenient operating hours and credit card acceptance. Especially, in the Chennai city, customers in the retail outlets have to face

the difficulties in terms of parking facilities and convenient operating hours. For these reasons, customer perception towards policy in retail service quality is in the moderate level comparing with the customer perception towards Infrastructure facilities, Management Responsibility, Employee - Customer Interaction, policy and problem solving in the retail service quality. Importantly, customer perception towards employees' knowledge & behavior, prompt service, individual attention, and complaint handling is in the highest level among the retail customers in the Chennai city. Due to that, retail service quality influences the customer satisfaction in the Chennai city significantly. Due to that, investments on the retail outlets aid to gain the return on investment and equity.

When the government frames the policies regarding to the fiscal and monetary, modern retail outlets should be considered through the concessions and other benefits. People in the Chennai city hold the better conditions in terms of demographic factors as income, social status, and life pattern etc. Studies in the other parts of Tamil Nadu might give the different findings. Before we come to the general conclusion in the Chennai context, studies among retail service quality should be taken in the various service industries, provinces and other places. Further, the concept like retail service quality should be connected with customer loyalty, customer retention and brand equity to get the more insights in the marketing practices of the retail outlets. Additionally, we suggested to the future researchers or scholars to carry the research on the factor analysis in order to find out the applicability of RSQS in the Chennai perspective.

SECTION – III

OPERATIONS PLANNING AND CONTROL

Inventory Control Model with Varying Rate of Deterioration and Mixed Demand Pattern

Pankaj S. Ardak¹, Atul B. Borade²

¹Department of Mechanical Engineering

²Department of Mechanical Engineering
Jawaharlal Darda Institute of Engineering and Technology Yavatmal, Maharashtra, India.

Abstract: This paper derives the optimal cycle time and total cost for an EPQ model with varying rate of deterioration and mixed demand pattern. Demand is inventory dependent during inventory buildup time and constant demand has been used for during inventory depletion period. Rate of deterioration is changing after particular time period. A numerical example has been provided to validate the model. The result of sensitivity analysis indicated that total cycle time and cost are sensitive to production rate, increase in deterioration rate and demand rate.

Keywords: EPQ, Mixed demand pattern, Varying rate of deterioration.

1. INTRODUCTION

In manufacturing sector, when items are produced internally instead of being obtained from an outside supplier, the EPQ model is often employed to determine the optimal production lot-size that minimizes overall production/inventory costs. The complexity of a resulting EPQ model depends on the assumptions one makes about various parameters of the inventory system. Among these features are demand types, actions for excess demand, production rates, treatment for imperfect quality items, minimal service level constraint, various cost parameters, and issuing policies when items are perishable. The classic EPQ model assumes that manufacturing facility functions perfectly during a production run. However, due to process deterioration or other factors, the generation of imperfect quality items is inevitable.

2. LITERATURE OF ECONOMIC PRODUCTION QUANTITY MODELS.

From product life cycle, demand rate will be constant only when product is in maturity stage. In the competitive scenario, higher stock of items attracts the customers to purchase more (Teng *et.al* 2005). Deterioration is the common phenomenon in the real production system of products like pharmaceuticals, food, flowers, vegetables etc. The effect of an imperfect production process, by assuming different rates of deterioration during the production process, on the optimal cycle time had been studied by (Rosenblatt and Lee, 1986). The EOQ model with power form of stock dependent demand for deteriorating items (Teng, *et.al* 2005), investigated that the shape parameter of the demand and selling price is highly sensitive to optimal solution. The impact of the random

machine failure on the EPQ model (Teng, *et.al* 2005) was that the demand function and purchase cost is positive and fluctuating with time. The production process can shift at random from in control to out of control state during production process. In such situation the items produced in out of control state deteriorate at higher rate than the normal rate, hence get consumed by demand under LIFO policy (Garry and Dah, 2006). Behrouz and Babak, developed economic production quantity (EPQ) model by considering both the depreciation cost of stored items and process quality cost. Depreciation cost and process quality cost was assumed to be continuous functions of holding time and of production run length. Yuan *et.al* (2011) derived the optimal manufacturing batch size and number of shipment with scrap using mathematical modeling and algebraic approach. Ata (2011) discussed EPQ model for multi products single machine with discrete delivery. Taleizadeh, Naja and Naiki focused on EPQ model with a production capacity limitation and a random defective production rate. Gede and Hui (2010) analyzed an EPQ model for deteriorating Items with stochastic machine unavailability and price-dependent demand. Jinn (2007), used time varying demand and cost to analysed EPQ model and characterize the influences of both demand and cost over the length of production run time and the economic production quantity. Hezari (2008) developed EPQ model by considering imperfect and defective items. Holding cost for defective items has not been considered. David *et. al* (2009) considered partial backordering with constant demand to study inventory model. Jiang tao (2009) consider a multi-item inventory system, where the vendor provides the retailer with delay in payment. Yao (2007) established a model for deteriorating items under delay in payment, in which the demand is a negative exponential function of

price. Jia (2009) reported a supply chain system with trade credit. Liao [6] established an EPQ model for deteriorating items with delay in payment. Ardak *et. al.* (2017) developed EPQ model by considering mixed demand pattern. Inventory dependent demand in inventory buildup time and constant demand during depletion period. Ardak & Borade (2017) considered time dependent holding cost to developed EPQ model.

Most of the inventory models considered various demand patterns like stock dependent demand, power form demand, ramp type of demand, time dependent demand, selling price dependent demand and exponential demand. It is well known that, the demand rate vary with change in inventory level. From the literature review, it is observed that the different demand pattern has not been discussed by any researcher so far on different time period. The present study may be significant in filling this gap since it aims to develop EPQ model by assuming demand as inventory dependent criteria during inventory buildup time and constant during inventory depletion period. This paper has five sections. Research motivation and literature is narrated in section 2. Section 3 contains notations and assumption. Methodology used to develop the model is discussed in section 4. Numerical and sensitivity analysis is discussed in section 5 and finally concluded in section 6

3. ASSUMPTION AND NOTATIONS

Following assumption and notations are used to develop the model.

3.1 Assumptions:-

The following assumptions are made in development of the model.

- The production rate is known and is constant.
- The production rate is greater than the demand.
- The demand is inventory level dependent in up time and constant in down time.
- Deterioration of the items is varying.
- Inventory holding cost is known and termed as constant.
- Deterioration of the items start as it enters into inventory.
- Shortages are not allowed.
- Every produced items needs inspection.

3.2 Notation

I_1 – Inventory level during production up time, I_2 – Inventory level during production down time, T_1 – Production up time. Maximum inventory buildup in this

time, T_2 –Production down time., T_2 –Production down time where rate of deterioration changes, P – Rate of production, D – Basic demand, θ – Basic rate of Deterioration, β – Increase in rate of deterioration, α – Inventory dependent consumption rate parameter., H – Holding cost per unit, C_i – Inspection cost per unit, T – Production cycle time., TC – Total cost., IC – Total Inspection cost, TCT – Total cost per unit time, TI – Total Inventory.

4. MODEL FORMULATION

This EPQ model considered inventory dependent demand and constant holding cost and different rate of deteriorating items. The production starts at time zero and inventory start to build up at the rate of $P - D$, which is the production rate minus consumption rate with deterioration up to time T_1 where the production process stops and the inventory on hand reaches its maximum level.. After T_1 , the inventory consumed under the action of demand and deterioration up to time T_2 . After time T_2 , the inventory level decreases with the constant consumption rate, D , but rate of deterioration increases until it becomes zero at time. The objective of this part of this research is to find the optimal inventory cycle time.

Fig. 1. Inventory System

As shown in fig.1, the production will start at $t = 0$, during the time period $(0, T_1)$ the inventory will gradually build up with constant deterioration. Later, production stops and buildup inventory is consumed to fulfill the demand. For the time period $(0, T_2)$, inventory will consumed under the action of constant demand and basic rate of deterioration. Maximum inventory will be at time $t = T_1$. For time period $(0, T_3)$, inventory get consumed under the action of constant demand and increase rate of deterioration. Production system can be described by the following differential equations.

$$\frac{dI_1(t)}{dt} = P - D - \alpha I_1(t) - \theta I_1(t) \quad 0 \leq t \leq T_1 \quad (1)$$

During time interval $(0, T_2)$, deterioration of items starts at basic rate. Hence the system is affected by the combined effect of constant demand and deterioration. Hence, the change in inventory level is governed by the following differential equation.

$$\frac{dl_2(t)}{dt} = -D - \theta l_2(t) \quad 0 \leq t \leq T_2 \quad (2)$$

In time interval $(0, T_3)$, demand rate is constant and rate of deterioration of items is at increase rate. Hence, the change in inventory level is governed by the following differential equation.

$$\frac{dl_3(t)}{dt} = -D - \beta l_3(t) \quad 0 \leq t \leq T_3 \quad (3)$$

Initial boundary conditions associated with this equations are, at $t = 0$, $I_1(t) = 0$, at $t = T_2$, $I_2(T_2) = Q$ and at $t = T_3$, $I_3(T_3) = 0$ the solution to above equations is as follows. These three equations are used in the derivation of our model.

$$I_1(t) = \frac{P-D}{\alpha+\theta} \left[1 - e^{-(\alpha+\theta)t} \right] \quad (4)$$

$$I_2(t) = \frac{-D}{\theta} + \left[Q + \frac{D}{\theta} \right] e^{\theta(T_2-t)} \quad (5)$$

$$I_3(t) = \frac{D}{\theta} \left[e^{\beta(T_3-t)} - 1 \right] \quad (6)$$

By using initial boundary conditions $I_3(0) = Q$ for equation 6

$$Q = \frac{D}{\beta} \left[e^{\beta(T_3)} - 1 \right] \\ = D \left[T_3 + \frac{\beta T_3^2}{2} \right] \quad (7)$$

By using boundary conditions $I_1(T_1) = I_2(0)$ and Eq.7 for equation 4 and 5,

$$\frac{P-D}{\alpha+\theta} \left[1 - e^{-(\alpha+\theta)T_1} \right] = \frac{-D}{\theta} + \left[Q + \frac{D}{\theta} \right] e^{\theta(T_2)} \\ T_2 = \frac{(P-D \times T_1)}{D} - T_3 - \frac{\beta T_3^2}{2} \quad (8)$$

Total Inventory is given by

$$TI = \int_0^{T_1} I_1(t) dt + \int_0^{T_2} I_2(t) dt + \int_0^{T_3} I_3(t) dt \quad (9)$$

Total Inventory holding cost is given by

$$IH = H \left[\int_0^{T_1} I_1(t) dt + \int_0^{T_2} I_2(t) dt + \int_0^{T_3} I_3(t) dt \right] \\ = H \left(\frac{P-D}{2} \times T_1^2 + D \left[T_3 + \frac{\beta T_3^2}{2} \right] \left(\frac{(P-D \times T_1)}{D} - T_3 - \frac{\beta T_3^2}{2} \right) + \frac{D}{2} \times T_3^2 \right) \quad (10)$$

All produced items need inspection, So inspection cost is given by,

$$IC = C_i \int_0^{T_1} I_1(t) dt \\ = C_i \left(\frac{P-D}{2} \times T_1^2 \right) \quad (11)$$

From equations 10 and 11.

Total cost = Set up cost + Holding cost + Inspection cost.

$$TC = A + IH + IC \quad (12)$$

$$= A + H \left(\frac{P-D}{2} \times T_1^2 + D \left[T_3 + \frac{\beta T_3^2}{2} \right] \left(\frac{(P-D \times T_1)}{D} - T_3 - \frac{\beta T_3^2}{2} \right) + \frac{D}{2} \times T_3^2 \right) + C_i \left(\frac{P-D}{2} \times T_1^2 \right)$$

$$\text{Production cycle time} = T = T_1 + T_2 + T_3 \quad (13)$$

$$T = T_1 + \frac{(P-D \times T_1)}{D} - T_3 - \frac{\beta T_3^2}{2} + T_3 \\ = T_1 \left(1 + \frac{P-D}{D} \right) - \frac{\beta T_3^2}{2} \quad (14)$$

Total cost per unit time is given by

$$TCT = \frac{TC}{T} \\ = \frac{A + K T_1^2 + K_1 T_1 T_3 - T_3^2 [K_2 + K_3 + K_4 T_1] - K_3 T_3^3 - K_5 T_3^4}{T_1 K_6 - \frac{\beta T_3^2}{2}} \quad (15)$$

Where,

$$K = (H + C_i) \frac{P-D}{2}, \quad K_1 = H(P-D), \quad K_2 = \frac{HD}{2}, \quad K_3 = \frac{HD\beta}{2}, \\ K_4 = \frac{H\beta(P-D)}{2}, \quad K_5 = \frac{HD\beta^2}{4}, \quad K_6 = 1 + \frac{P-D}{D}$$

Total cost per unit time is function of T_1 and T_3 . The optimum production up time can be derived by satisfying the equation.

$$\frac{dTCT}{dT_3} = 0 \text{ and } \frac{dTCT}{dT_1} = 0 \quad (16)$$

By solving equation No. 15 and 16 simultaneously optimum value of T_1 and T_3 can be obtained.

$$\frac{dTCT}{dT_3} = \frac{d}{dT_3} \left[\frac{A + KT_1^2 + K_1T_1T_3 - T_3^2[K_2 + K_3 + K_4T_1] - K_3T_3^3 - K_5T_3^4}{T_1K_6 - \frac{\beta}{2}T_3^2} \right] = 0$$

$$\frac{dTCT}{dT_1} = \frac{d}{dT_1} \left[\frac{A + KT_1^2 + K_1T_1T_3 - T_3^2[K_2 + K_3 + K_4T_1] - K_3T_3^3 - K_5T_3^4}{T_1K_6 - \frac{\beta}{2}T_3^2} \right] = 0$$

Ignoring higher power of T_3 & T_1 and after some approximation, following quadratic equation can be obtained.

$$T_3 = \sqrt{\frac{AK_6}{K_2K_6 + K_3K_6 - \frac{\beta}{2}K}} \quad (17)$$

$$T_1^2(K_1K_6) - T_1[2K_2K_6T_3 + 2K_3K_6T_3 + K\beta T_3] - A\beta T_3 = 0 \quad (18)$$

Closed form solution can be obtained by considering positive root of equation 18.

5. NUMERICAL AND SENSITIVITY ANALYSIS

Numerical example and sensitivity analysis has been carried out to validate the theoretical aspects. The numerical data is adopted from Ardak *et al.*(16) Let, $A = \text{Rs.}30$ per production cycle, $P = 2500$ units per unit time, $D = 1200$ units per unit time, $\alpha = 0.5$, $\theta = 0.1$, $a = 2$ $b = 1.5$. and $\beta = 0.2$ The optimum value of T_1 can be found. The optimum value of T_1 is 1.4. The optimum total cost per unit time is $TCT = \text{Rs.}2411$. Sensitivity analysis is carried out by changing each parameter by -40% to $+40\%$, taking one parameter at a time and keeping others unchanged.

TABLE 1: Sensitivity analysis of T_1

Parameters	Parameter changes							
	-40%		-20%		20%		40%	
	T_1	TCT	T_1	TCT	T_1	TCT	T_1	TCT
P	4.42	1794.77	1.99	1986.96	1.1	3015.83	0.96	3767.80
D	1.06	3745.65	1.21	2841.55	1.7	2236.12	2.14	2209.72
β	1.34	2330.63	1.37	2371.09	1.4	2450.42	1.46	2489.23
H	1.86	2209.04	1.58	2301.22	1.3	2525.52	1.17	2640.02
Ci	1.38	2155.99	1.39	2282.64	1.4	2541.15	1.42	2673.05

From figure 1, it can be commented that production up time is highly sensitive to production rate and demand rate. While production up time is slightly sensitive to deterioration rate and holding cost.

Fig. 1. Parameter change V/ T_1

Fig. 2. Parameter change V/sTCT

For first 20% increases in production rate change in production up time is more as compared to last 20% change in production rate. This may be due to inventory dependent demand. Figure 2 indicates that TCT is highly sensitive to

demand rate and production rate. Increase in rate of deterioration also increases T_1 and TCT. This attracts attention of inventory managers.

6. CONCLUSION

In this study, theoretical EPQ model has been developed over an infinite time horizon. Some interesting observations are presented. During inventory buildup time, demand used was inventory dependent and during inventory depletion time it was constant. Sensitivity analysis shows that TCT as well as production up time are highly sensitive to production and demand rate. Increase in rate of deteriorations increases the TCT and optimum cycle time. This model can be useful for the inventory managers in decision making especially for the perishable items. The model can be further developed by considering different deterioration rate, production rate.

³Fr. Conceicao Rodrigues College of Engineering, Mumbai, Maharashtra, India

Abstract: An Aggregate production planning helps to balance the capacity and demand to minimize the overall cost with reference to inventory and labor levels, overtime, subcontracting, backordering levels and other resources. To generate the solutions, linear programming models are used. This paper presents the methodology to develop aggregate production plan by using Mathematical modeling using Linear Programming followed by Arena simulation software.

Keywords: Aggregate Production Planning, Manufacturing, Linear Programming, Simulation, ARENA.

1. INTRODUCTION

Every organization needs planning to operate the system. Every manufacturer need to satisfy consumer demands. This requires the efficient operation of a supply chain planning. At different levels of aggregation companies create several plans with the help of different planning horizons. The term aggregate production planning (APP) is medium-range capacity planning which typically covers a time horizon of 2 to 18 months. The aim of aggregate production planning is to achieve a production plan in which the organization's resources will be effectively utilized to satisfy the given demand. Aggregate production planning helps to balance the capacity and demand to minimize the overall cost with reference to inventory, labor levels, overtime, subcontracting, backordering levels and other resources. The Aggregate production planning is the big picture approach to planning. Aggregate production planning is high level planning activity in the production management system. This paper presents the methodology to develop aggregate production plan by using Mathematical modeling using Linear Programming followed by Arena simulation software.

2. LITERATURE REVIEW

Simulation is the imitation of the operation of a real-world process or system over time. Simulation is an attempt to model a real-life situation on a computer to study how the system works. By changing the variables, predictions may be made about the performance of the system. Many books and research papers deal with the general topic of simulation. There are several annual conferences exclusively dealing with the simulation technology, tools and applications.

Lin Pan and Brian H. Kleiner (2012), writes about today's aggregate planning, its objective, characteristic and techniques. In this paper, the brief introduction of aggregate

planning is given. AtthawitTechawiboonwong and PisalYenradee (2002), writes APP model and a guideline to develop an optimal aggregate production plan using the spreadsheet solver and the manufacturing case study presented to demonstrate how the guideline can be applied. Xueying T. et al. (2010), writes about the development and application of a simulation-based aggregate planning approach that facilitates modeling and coordination of a batch plant's supply chain. J.S. Smith (2003) has done a study on modeling and development aspects pertaining to manufacturing systems simulation. Heilala J. (2010) at winter simulation conference explains, the development of simulation based decision making system for customer driven manufacturing planning. Moradi and Schubert (2015) at Swedish Defense Research Agency explained Simulation-based decision support for evaluating operational planseffectively. Maciej Nowak (2013), studied a new approach for production aggregate planning problem is proposed. Gadinaikand Bilolikar (2015) explains how to improve performance parameters like resource utilization, delivery time and inventory for a batch type manufacturing system. Molly Arthur (2014) presented a paper Simulation-Based Decision Support System for JSF Production, explaining the modification done in the production schedule. Mourtzis D. and Bernidaki D. (2014), explains the challenges in Simulation of Manufacturing systems. Shirazi B. and I. Mahdavi (2010) explains Development of a Simulation-Based Intelligent Decision Support System for Flexible Manufacturing Systems. Negahban A., Smith J. (2013) did the literature review and survey on the simulation of manufacturing system design and operation. More than 300 papers are reviewed in this paper. Bai et al. (1996), use simulation to analyze the performance of production system under different control policies. The objective of the research was to evaluate the feasibility of using simulation for production control policy selection.

3. METHODOLOGY

The foremost concern of this research is to study how the production capacity can be improved by changing operating policies, for this we are using two methodologies. One is mathematical modeling and other is simulation methodology. The mathematical modelling involves the use of Linear Programming method in which a set of objective functions subjected to the set of constraints is solved. Our study deals with the minimization of overall cost of production, overtime, subcontracting and fluctuations in production. The constraints applied to the problem are related to regular production hours, demand, capacity of satisfying the maximum demand, limitation on the fluctuation of demand. The spreadsheet solver is used to solve the linear programming problem.

The basic assumptions considered are as follows:

- The forecast of the demand has been made for the next T periods.
- The model should provide a plan that minimizes the particular objective.
- The customer service is at utmost importance for the company. Therefore, the final inventory in month t should be high enough to guarantee high probability of meeting the demand in next month.
- The prime objective is to minimize total cost, which includes production cost, inventory cost and the cost involved in idle situations. Shortages are not allowed in this model, so the cost of delays in deliveries is not taken into consideration.
- The production is measured in production hours required for its completion.

The notations used in the model are as follows:

R_c^{pi}	=	the regular time production cost per labor-hour of i^{th} part,
E_c^{pi}	=	the overtime production cost per labor-hour of i^{th} part,
H_c^{pi}	=	the subcontractor production cost per labor-hour of i^{th} part,
K_c^{pi}	=	the inventory holding cost per month of one labor-hour of work of i^{th} part,
I_c^{pi}	=	the idle regular time production cost per labor-hour of i^{th} part,
D_c^{pi}	=	the cost delayed delivery per one production hour of i^{th} part,
R_t^{pi}	=	the regular time production hours scheduled in month t of i^{th} part,
E_t^{pi}	=	the overtime time production hours scheduled

in month t of i^{th} part,

H_t^{pi}	=	the subcontractor time production hours scheduled in month t of i^{th} part,
K_t^{pi}	=	the number of working hours stored in inventory at the end of month t of i^{th} part,
I_t^{pi}	=	the number of idle time regular production hours in month t of i^{th} part,
W_t^{pi}	=	the expected demand in month t (hours of production) of i^{th} part,
M_t^{pi}	=	the highest demand the company should be able to satisfy in month t (hours of production) of i^{th} part,
MR_t^{pi}	=	the maximum number of regular time hours in month t of i^{th} part,
ME_t^{pi}	=	the maximum number of overtime hours in month t of i^{th} part,
MH_t^{pi}	=	the maximum number of subcontractor hours in month t of i^{th} part,
a_t^{pi}	=	the reduction in the number of production hours scheduled in month t compared to the number of production hours scheduled in month t – 1 of i^{th} part,
b_t^{pi}	=	the increase in the number of production hours scheduled in month t compared to the number of production hours scheduled in month t – 1 of i^{th} part,
K_0	=	initial inventory,
T	=	The number of months in the planning horizon.
P	=	The number of parts under considerations
p_i	=	i^{th} part ($i = 1, \dots, P$)

The objective functions are:

$$f_1 - \text{Total cost: } f_1 = \sum_{t=1}^T \sum_{p=1}^P (R_c^{pi} R_t^{pi} + E_c^{pi} E_t^{pi} + H_c^{pi} H_t^{pi} + K_c^{pi} K_t^{pi} + I_c^{pi} I_t^{pi}) \quad 4.1$$

$$f_2 - \text{The total number of overtime production hours: } f_2 = \sum_{t=1}^T \sum_{p=1}^P (E_t^{pi}) \quad 4.2$$

$$f_3 - \text{The total number of subcontractor production hours: } \quad (4.3)$$

$$f_3 = \sum_{t=1}^T \sum_{p=1}^P (H_t^{pi})$$

The total fluctuations in production rates:

$$f_4 = \sum_{t=1}^T \sum_{p=1}^P (a_t^{pi} + H_t^{pi} + E_t^{pi}) \quad (4.4)$$

The constraints subjected to the objective functions are as follows:

$$K_{t-1}^{pi} + R_t^{pi} + H_t^{pi} + E_t^{pi} - K_t^{pi} = W_t^{pi} \quad (4.5)$$

$$K_{t-1}^{pi} + R_t^{pi} + H_t^{pi} + E_t^{pi} \geq M_t^{pi} \quad (4.6)$$

$$R_t^{pi} + I_t^{pi} = MR_t^{pi} \text{ for } t = 1, \dots, T \quad (4.7)$$

$$R_t^{pi} + H_t^{pi} + E_t^{pi} + a_t^{pi} - b_t^{pi} = R_{t-1}^{pi} + H_{t-1}^{pi} + E_{t-1}^{pi} \text{ for } t = 2, \dots, T \quad (4.8)$$

$$K_0^{pi} = K_1^{pi} = 0, a_1 = 0, b_1 = 0 \quad (4.9)$$

$$0 \leq R_t^{pi} \leq MR_t^{pi}, 0 \leq E_t^{pi} \leq ME_t^{pi}, 0 \leq H_t^{pi} \leq MH_t^{pi} \text{ for } t = 1, \dots, T \quad (4.10)$$

$$a_1 \geq 0, b_1 \geq 0, I_t \geq 0 \text{ for } t = 1, \dots, T \quad (4.11)$$

$p = 1, \dots, P \forall$ equations.

Here $P = 4$, as we considered 4 parts. These parts are regular parts.

As stated earlier, the research starts with forecasting the demand for T period followed by developing an aggregate production plan using linear programming approach. The study also helps to increase the utilization rate by reducing the idle situations and downtime.

The study is carried out in a company which produces manifold assemblies for AC's in cars. In recent days, the company finds it difficult to provide the demanded parts in said period. This in turns results in customer dissatisfaction. The aim of the study is to create the proper aggregate production plan in order to meet customer demand in said time.

3.1 Data Collection

For creating the model, most of the data taken was real time shop floor data which is collected by observation. It includes collecting the processing time on the resources per product which takes around 2 to 3 months of careful observation. Secondary data like layout of the plant of the facility, machines in the company, total manpower, were collected from senior members of the organization, while standards and product list were obtained from the company executives. Data collected are classified into Primary, Secondary and Tertiary type in table 1.

TABLE 1: Type of Data

Primary Data	Processing Time, Setup Time, Batch Size, Modification in Plant Layout, detailed Process Flow Diagram.
Secondary Data	Plant layout, Working Hours per day, Demand pattern, Number of resources, Material Information, Scheduled Maintenance.
Tertiary Data	Product List, Material Information, System Used, tool used, Standard used, throughput time.

For this, a company's manufacturing set up is modeled in ARENA i.e. virtual model is created. The model is studied and analyzed for various input situations. The results are tested and the solutions are formed. "ARENA Simulation Software" is used for creating the Manufacturing system's model shown in figure 1.

Fig. 1. ARENA Model of a firm

After studying the current scenario over which the company is working, it is found that, the company is unable to meet the demand level that customer wants. Also, few resources are bottlenecked. Some resources are found to have the utilization over 99.98% while some have 12%. There are some resources which are idle and having 0% utilization which leads to incompleteness of customer's orders. This unbalanced condition in utilization of resources leads to plan the entire production to balance the resource utilization as well complete the orders.

Now using anExcel Solver, the linear programming model is solved. The results obtained are fed in Arena and the new Scenario has been recorder. The process analyzer tool has been used to check the different scenarios.

4. RESULTS AND DISCUSSIONS

The company was struggling to fulfill the customer's demands. This caused serious customer dissatisfaction which further caused customer loss to the company. The forecasted demand and the result are shown in table no. 2 and 3 respectively. From the ARENA process analyzer, it is observed that some machines are over utilized, some are underutilized and some are idle which rectified after

implementing the plan produced from Linear Programming model. The first scenario is without any heuristic. From the next, the scenarios are made by implementing the LPP Plan. Results are shown in tables 4, fig. 3, and fig. 4. The results generated by the proposed method of aggregate production planning indicates that the model provides a promising approach to fulfill the efficient production planning objectives in a complex manufacturing system.

The results are then fed into arena, and the resource utilization and the delivery schedule has been tested. Table no.3 and Figure no. 3 gives the utilization result from arena. Here, we observe that all the machine utilization is way

below 1 and greater than 0, i.e. the machines are not over utilized nor unutilized. Also Figure No.4 shows parts produced in different scenarios.

Fig. 2. Machine Utilization in Different Scenarios

Fig. 3. Parts Produced in Different Scenarios vs. Run Length

5. CONCLUSION

The aim of Aggregate production planning is to achieve a production plan to meet fluctuating future demand in which organization's resources will be effectively utilized. This study helps to discover the lowest-cost plan. Also, Simulation model helps to check the various plans, its impact over the system and the best fit plan without disrupting the setup. By using Simulation, the future study in the field of waiting time behavior, new resources, their utilization and the status of inventory over them and layout changes can also be done. to test operational plans as to their robustness.

An ANP Approach for the Assignment of Projects to Teams in an Organization

Lavanya Meherishi, Vishwas Dohale

National Institute of Industrial Engineering, Mumbai, Maharashtra, India

Abstract: Every Organization deals with projects and there is a need for the organization to assign the right projects to the right teams which can handle the projects efficiently. After having a clear understanding of the projects and the team capabilities, Decision Maker underpins this assignment process. Multi criteria Decision Making offers a range of methods to come to an optimal solution for the same.

Keywords: Assignment model, Multi criteria decision making, AHP, ANP.

1. INTRODUCTION

Every Organization has a set of projects or tasks to complete in a certain time-period. These projects may be dealt with by the organization one by one or simultaneously. It depends on the functioning style of the Organization and the size of that organization in the market. In today's competitive world most of the organizations deal with multiple projects simultaneously. Thus, formulation of teams becomes an obvious step and the next bigger step and perhaps a critical step is the appropriate assignment of the projects to the teams. Any wrong decision in this assignment leads to delayed completion of projects or even become bottlenecks (in case the projects are a part of bigger projects) which could heavily impact the organization's reputation in an ever-un-stable market today.

Up until now, the assignment of projects to teams is done either randomly or depending on the past-experience of the decision maker. The projects being worked upon will have their own attributes and so will the teams. The attributes of the team will be holistically derived from those of its team members. So, it becomes unavoidable to consider the attributes of both projects and teams to get the right match between the two. Here is where Multi Criteria Decision Making plays a key role. Multi Criteria Decision Making (MCDM) is a tool in Operations Research. It considers multiple conflicting criteria or factors that need to be evaluated to make decisions. One of the main tools that MCDM offers under it is 'Analytic Hierarchy Process' or AHP.

In the AHP approach, the decision problem is structured hierarchically at different levels with each level consisting of a finite number of decision elements. The upper level of the hierarchy represents the overall goal, while the lower level consists of all possible alternatives. One or more intermediate levels embody the decision criteria and sub-criteria. The weights of the criteria and the scores of the

alternatives, which are called local priorities, are considered as decision elements in the second step of the decision process. The decision-maker is required to provide his preferences by pair-wise comparisons, with respect to the weights and scores. But AHP has a set-back. It only considers decision making in a hierarchical structure. It does not account for those decision-making problems involving multiple criteria and alternatives with feedback and interdependence. In such cases, Analytic Network Process or ANP can be applied. Most of the MCDM techniques work well under the assumption of judgmental independence of criteria. ANP is one such MCDM techniques which considers the influence and dependence of the factors on each other.

This paper explores the relationships between the attributes of the projects and those of the teams and tries to come up with an optimal match between the two using ANP.

2. LITERATURE REVIEW

The problem consists of set of Teams that are supposed to perform a set of projects. It is given that each Team has a given capacity in terms of the maximum number of projects that can be allotted to the teams such that no team is left unassigned. This problem can be modelled as a Generalised Assignment model. Kuhn(1955) presented the Hungarian method where the number of tasks is equal to the number of employees and the goal is to minimize the total cost incurred. Chauvet et al.(2000) address two real life Bottleneck assignment problems in their paper. In both the cases the number of employees who should perform the task is significantly greater than the number of tasks to be performed. Jeonghwan et al.(2016) have proposed an approach based on the analytic network process (ANP) to rank a set of potential A&D candidates within a multivariate set of attributes systematically. A total of 25 criteria were identified and used to construct the ANP model in which the final selection is based on the resulting

priorities assigned to the A&D candidates. Beltrán et al. (2017) have studied the influence of stakeholders within a project using ANP to obtain an index for each stakeholder which represents his individual influence with respect to the rest of the stakeholders of the group. Hosseini et al. (2013) have explained how the various super matrices can be calculated by applying ANP to select the best strategy to reduce risks in a supply chain. Acar and Aplak (2016) have applied ANP to study the Multi-Objective and Multi-Criteria Vehicle Assignment Problem in a Security Organization scenario. Acar and Aplak have used the SuperDecisions software to find out the criteria weights and the performance values.

3. METHODOLOGY

The ANP (Saaty, 2001) is a generalisation of AHP. The problem in ANP is depicted and analysed as a network. The network structure is obtained because of the interdependence between the various criteria and the alternatives which are grouped into clusters depending on some common feature.

The methodology involves the following steps:

- STEP 1: Understanding the problem
- STEP 2: Formulation of ANP model
- STEP 3: Using the ANP software for the calculation of the main/sub Criteria weights.
- STEP 4: Evaluating the performance values (Using ANP software) of assigned projects for each team.
- STEP 5: Modelling the assignment and realising the optimal project assignment.

3.1 Understanding the Problem:

The problem being faced by the organisations is that they have to complete say, P projects simultaneously and the reigns of these projects are to be handed over to T teams (where, $P > T$) with different number of members in them. The Decision maker i.e.; the Team Manager randomly or at the least based on his past experience with the teams, assigns the projects to the teams. There are several problems that arise due to this random assignment. At times, one

team which is relatively better than others in some attributes may be handling most of the projects while the other teams may have relatively less work load. This hampers the efficiency of the teams and ultimately the organisation and may also cause delayed completion of the projects.

3.2 Formulation of ANP model:

Once the main goal is determined, the decision maker is approached for determining the criteria and sub criteria and the relationships and interdependencies among these factors is established. The ANP model has been obtained in Figure No 1. The study involves an illustrative case of 10 projects and 5 Teams.

3.3 Using the ANP software for the calculation of the main/sub Criteria weights:

After relations between criteria are revealed, the face to face interview is conducted with the decision maker and questions are asked in order to measure the pair-wise comparisons between criteria. The question of how many times a criterion is more important than the others has been answered with pairwise comparisons of criteria. Pairwise comparisons are formed in Super Decision software and each pairwise comparison is performed. The pairwise comparisons have been entered in the software using the Questionnaire Format. After all the pairwise comparisons are made, the Unweighted, weighted and Limit Super-matrices can be obtained from the Super -Decisions software. The limit super matrix of the model is obtained from the software is presented in Figure 2. Row values obtained from the limit super matrix give the priority coefficient to select the best alternatives.

The software then gives the local and global weights of each of the elements in all the clusters which are presented in Table No. 1. The local weights are the weights of each elements in their respective clusters whereas the global weights are the overall weights of the elements in the entire model. The global weights are considered for further calculation.

3.4: Evaluating the performance values (Using ANP software) of assigned projects for each team:

The performances of all alternatives against each project are evaluated under criteria by using the “ratings” section in ANP’s software. Standards of performance for each alternative is established for each criterion and the alternatives are rated one at a time with respect to each criterion using these standards. An illustrative example is shown in Figure No. 4. This Figure depicts the Performance Value of all the 5 Teams with respect to Team efficiency cluster for Project P1. Similarly, performance values (Priorities) of the teams with respect to each element in each cluster is obtained for each of the projects.

	Priorities	Totals	PAST EXPERIENCE 0.282276	PREVIOUS PERFORMANCE 0.062122	PROBLEM SOLVING 0.082820	TECHNICAL SKILL 0.525944	NUMBER OF STAFF 0.046838

Fig. 4: Performance Values of Teams w.r.t. P1

3.5 Modelling the assignment and realising the optimal project assignment:

The company wishes to maximise its Profit Margin and Budget foreach project along with enhancing its Team Profiles. Thus, we have two criteria to maximize: Team Performances and Cost. On the other hand, the company wishes to reduce the time it takes to complete a project with the ulterior motive of completing more projects in the same time frame. It also wishes to minimize the risks and the complexities it faces while taking charge of these projects. Hence, we have two criteria to be minimized: The Time criterion and the Others criterion. Thus, our mathematical linear program is a Bi-Objective Linear Program. Another point that the company wishes to keep in mind is that every team should be assigned at-least one project but not more than Four projects.

Sets and Parameters:

I=set of projects = { 1, 2, 3,....10}

J=set of teams = { 1, 2, 3, 4, 5 }

G=set of main criteria={P, T, C, O}

P_{ij} = Performance Value of Team Profile when ith project is assigned to jth team.

C_{ij} = Performance Value of Cost when ith project is assigned to jthteam.

T_{ij} = Performance Value of Time when ith project is assigned to jthteam.

O_{ij} = Performance Value of Others when ith project is assigned to jthteam.

W_g =weight of the gth criteria

Decision Variable

$$X_{ij} = \begin{cases} 1, & \text{if } i^{\text{th}} \text{ project is assigned to } j^{\text{th}} \text{ team} \\ 0, & \text{Otherwise} \end{cases}$$

The linear programming model obtained for the given problem is:

$$\text{Max } z = (\sum_{j=1}^5 \sum_{i=1}^{10} P_{ij} X_{ij}) w_P + (\sum_{j=1}^5 \sum_{i=1}^{10} C_{ij} X_{ij}) w_C$$

$$\text{Min } z = (\sum_{j=1}^5 \sum_{i=1}^{10} O_{ij} X_{ij}) w_O + (\sum_{j=1}^5 \sum_{i=1}^{10} T_{ij} X_{ij}) w_T$$

Subject to constraints;

- $\sum_{j=1}^5 X_{ij} = 1$, for all $i=\{1,2,3,4,....10\}$
- $1 \leq \sum_{i=1}^{10} X_{ij} \leq 4$, for all $j=\{1,2,...., 5\}$
- $X_{ij} \in \{0,1\}$

4. DATA

The Data has been obtained from the priority values for each project corresponding to each team from the Performance Value Analysis done in the ANP software shown in Table 2. It consists Ten columns and Five rows each. The columns represent each of the Ten projects considered in the problem and the rows in each of the tables corresponds to each team i.e.; Team 1, Team 2, Team 3, Team 4 and Team5 respectively. In Table 2, P_i denotes the project number (where $i=1, 2, 3,....10$) and T_k denotes the team number (where $k=1, 2, 3, 4, 5$)

5. RESULTS AND DISCUSSION:

We solve the Bi-objective problem obtained in section 3.5 by the epsilon constraint method which helpsto solve the multi-objective linear programming problems. The model is coded and solved in LINGO 11.

Solving the Minimization problem first we get the following solution in the software,

!Global optimal solution found.
Objective value: 0.4012607
Objective bound: 0.4012607
Infeasibilities: 0.000000
Extended solver steps: 0
Total solver iterations: 16

Using the minimization objective as an additional constraint and solving the maximization problem, we get the following solution

!Global optimal solution found.
Objective value: 1.262002
Objective bound: 1.262002
Infeasibilities: 0.000000
Extended solver steps: 0
Total solver iterations: 52

6. CONCLUSION

On solving the given Mathematical assignment model developed for this problem, the final result is obtained given below,

$$X_{11}=1$$

$$X_{62}$$

All other decision variables are zero.

$$X_{72}=1$$

$$X_{24}=1$$

$$X_{34}=1$$

$$X_{85}=1$$

$$X_{43}=1$$

$$X_{93}=1$$

$$X_{55}=1$$

$$X_{10,1}=1$$

Hence, the optimal assignment satisfying the constraints is obtained as shown in table no. 3:

TABLE 3. Optimal Assignment of Projects to Teams

Teams	1	2	3	4	5
Project Assigned	1 and 10	6 and 7	4 and 9	2 and 3	5 and 8

An Empirical Investigation of Small Manufacturers for Operational Reliability

Kshtraveer Singh¹, Piyush Singhal²

^{1,2}Department of Mechanical Engineering, GLA University, Mathura, Uttar Pradesh, India

Abstract: Reliability of a supply chain depends on the reliability of its various components. To be responsive and cost effective. It is very essential to estimate the reliability of the whole chain as well as the individual player. This is very essential to conduct suitable reliability tests and modify them as per the dynamic environment. For this work a statistical tests are conducted with the help of data collection for various elements. On the basis of that the overall reliability is also estimated. Then various suggestions based on investigation are proposed to improve the reliability and acceptability of the small suppliers in supply chain.

Keywords: Reliability, Uncertainty, Risk Assessment, Supply Chain Management

1. INTRODUCTION

Supply chain management Is the key of thought in today's story with basic purpose to integrate all elements of supply chain to improve the supply chain value increase. Supply chain is play important role globally and stimulates the dangerous opportunities in India also. The global manufacture are reduce the cost and increased their quality continuously. Therefore the cut throat competition they are India. Large scale of manufacturers are taking full advantages in India. The changing global story but despite many policy measures for the part of decades, the significant not shown by small scale units. Its improvement to share the global market with large manufactures. This department is very small, and technologically back ward. In which, some of the large problems faced by the factor are access to timely and adequate credit, technological obsolescence, infrastructural. Large scale manufacturers having a cyclonic market. And multiplicity of rules and regulations. Because Condition of this situation the sector of Indian manufacturing could not melt the global expectation and absent the opportunities which really knocking our doors. The small scale industries having special things is that, it highly fragmented and having a pyramidal structure. It means that establishment size is minimize number of unit goes up. The maximum competition occurs by this structure at small and mini sectors. This competition minimum the profit margins, which makes the worst condition. The player of Indian or global in small scale units is supply uncertainty compels the company to keep the high volume of safety inventories. It is very hardly accepted by any big player. In supply chain manufacturing, the small suppliers are considered as the uncertainty generators. Reason is that competency removed from the supply chain. The support of government is proper for small scale industries but it is not enough. In this area, the medium and large manufactures and academia should

study for resolve their problems. We can say that this sector can also become an effective and skillful player of supply chain and exploits the advantages of globalization and liberalization.

On the basis of study conducted for a small scale manufacturing unit manufactures auto parts of this paper. This paper is situating at Mathura. In which, the study one of supply uncertainty and analyzed as a supplier selection metrics and over all supply chain performance.

Benski and Cabau [1] emphasis to use the field data to estimate the Reliability and analyze the supply chain performance through it as it gives more realistic results.

1.1. Initial Investigations

The unit basically manufactures various small auto parts for bigger suppliers situated at Noida. From last four years this unit has been facing a tremendous problems related to the quality of products, scheduling, lead time, frequent failures and breakdowns. Because of the above mention reasons and increasing competition this unit lost almost all of its orders and out of the market.

Following points are come out after the initial phase of discussions with the proprietor and senior persons of the unit.

- Initially the unit was doing well with expertise in machining products.
- Later on situation become tough because of increasing competition.
- Company could not manage to manufacture and deliver the products timely.
- Quality and costing were also vulnerable issues.

It is decided to conduct Reliability Tests with past failure data of various machines and then analyze its effect on the supply chain. Manufacturing Unit under consideration is having various machines like Milling machines, lathe machines, Drilling machines, furnaces etc. The layout of the unit is process type to support manufacturing of the variety to products of small batch sizes. Apart this it also have small product lines dedicated to large order size items. For the present work one of such product line is considered three machines are considered in a series combination.

2. MATHEMATICAL ANALYSIS

Rajpal et al[2] developed an artificial neural network for simple systems. But it could not work with actual complex systems. For this Statistical model based on Weibull distribution is developed. Validity of this model has been done with goodness of fit tests conducted.

2.1. Steps of the Analysis

- Empirical Reliability is estimated with the help of failure data available using Rank Increment method. Initial estimation of Weibull parameters i.e. shape parameter and scale parameter are done using least square methods and normal equations.
- Statistical tests are conducted to determine the Maximum Likelihood Estimator (MLE) of the parameters. Mann's Goodness of fit test is conducted to verify the assumption that failure data is following two parameter Weibull distribution or not.
- Reliability and MTBF (Mean Time Between Failure) are estimated as per weibull Distribution.
- Over all Reliability of the system is estimated.
- Supply lead time and lead time variability is analyzed with the status of reliability. Relation between buyer's safety inventory and supply lead time and supply time variability is analyzed. Further the implications are studied for a supplier to be selected in a supply chain and remain the part of it for a longer time.

2.2. Rank Increment Method.

This method is used initially to drive the cumulative failure and then empirical reliability with or with out censored data. Since a censored unit has some probability of failure before or after the next failure, it will have influence the rank of the subsequent failure.

Rank Increment= [(n+1)–rank of previous failed]/[(n+1)–All the previous failed or withdrawn]

----- (1)

Here n = total number of units put on test

Now the adjusted rank is

$$i_t = i_{t-1} + \text{rank increment}$$

i_t = Rank of failures

i_{t-1} = Rank of previous failure

The empirical reliability function can be given as

$$\text{Reliability} = 1 - [(i_t - 0.3) / (n + 0.4)] \quad \text{-----} \quad (2)$$

The reliability of any unit can be derived at different failure times in a tabular form.

2.3. Weibull MLE

The MLE Of two parameter Weibull distribution can be calculated numerically. For shape parameter β the equation is

$$[\Sigma (t_i^\beta \ln t_i + (n-r) t_s^\beta \ln t_s) / \Sigma (t_i^\beta + (n-r) t_s^\beta)] - (1/\beta) - (1/r) \Sigma \ln t_i = 0 \quad \text{-----} \quad (3)$$

MLE estimate of Scale Parameter

$$\theta = \{1/r[\Sigma t_i^\beta + (n-r) t_s^\beta]\}^{1/\beta} \quad \text{-----} \quad (4)$$

Here r = number of failures, n = number of items on testing t_i = failure time of i th item, $t_s = 1$ for complete data

For complete failure $r = n$

2.4. Mann's Test for Weibull Distribution

This is a special test for Weibull distribution developed by Mann, Schafer and Singpurwalla (1974). Ebling [1] The hypothesis is given as

H_0 : the failure times come from Weibull distribution.

H_1 : the failure times did not come from the Weibull distribution.

The test statistic is

$$M = K_1 \Sigma [(\ln t_{i+1} - \ln t_i) / M_i] / K_2 \Sigma [(\ln t_{i+1} - \ln t_i) / M_i] \quad \text{-----} \quad (5)$$

$$\text{Where } K_1 = [r/2] \quad K_2 = [(r-1)/2] \quad \text{--} \quad (6)$$

$$M_i = Z_{i+1} - Z_i \quad \text{-----} \quad (7)$$

$$Z_i = \ln[-\ln(1 - (i-1)/(n+0.25))] \quad \text{-----} \quad (8)$$

Here $[r/2]$ is the integer part of the number $r/2$.

M_i is an approximation.

if $M > F_{\text{crit}}$ the hypothesis H_1 is accepted otherwise H_0 is accepted.

The values of F_{crit} can be obtained from the tables of F distribution where the degree of freedom for numerator be 2 K_2 and number of degree of freedom for denominator be 2 K_1 .

2.5. Impact of Supply Lead Time Uncertainty on Safety inventory

Uncertainty in supply lead time affects the performance of the supply chain drastically. This forced the buyer to stock the safety inventory as per the supply time uncertainty, the situation becomes worst with high variability in supply lead time. In actual cases buyers never tolerate these types of suppliers as lot of money blocked in safety inventories. As the result of this these supplier loses their stake in the supply chain.

2.5.1. Cycle Service Level

It is very important metrics to judge the quality of supplier. CSL is the probability that of not having a stock out in replenishment cycle. It is the fraction of replenishment cycles that ends with all the customer demand met. It is measured over a specified numbers of replenishment cycles [9].

2.5.2. Expected Safety Inventory

To understand this problem an inventory model is considered to predict the safety inventory under supply lead time uncertainty. Ref[9]

Let the Avg demand per period = D
 Std Deviation in demand per period = σ_D
 Avg lead time for supply replenishment = L
 Std. deviation in supply lead time = S_L
 Considering both supply and demand lead time uncertain
 Demand during lead time can be estimated as $D_L = D.L$ --
 ----- (9)

$$\text{Std Deviation } \sigma_L = (L \cdot \sigma_D^2 + D^2 \cdot S_L^2)^{0.5} \quad (10)$$

$$\text{Safety stock of the inventory } SI = ES^{-1}(\text{CSL}) \cdot \sigma_L \quad (11)$$

(Here CSL is cycle Service Level and ES^{-1} is an excel function to get the Inverse of the standard normal cumulative distribution)

3. DATA ANALYSIS

3.1 Reliability Analysis

3.1.1 Weibull distribution MLE and Mann's Test Statistic

(For Lathe Machine)

Solving by iterations with the help of Excel data sheet, the value of MLE $\beta = 1.519$

Now putting this value of β in equation

$$\theta = (18635.3)^{.6583} = 533.87 \text{ Hrs}$$

(Similarly these parameters can be calculated for other machines.)

After finding MLE of the Distribution parameters a goodness of fit test is conducted which is basically a statistical test.

Here Mann's test is considered to test the Weibull failure distribution.

Test statistics are $M = K_1 \sum [(\ln t_{i+1} - \ln t_i) / M_i] / K_2 \sum [(\ln t_{i+1} - \ln t_i) / M_i]$

Where $K_1 = [r/2]$

$K_2 = [(r-1)/2]$

$M_i = Z_{i-1} - Z_i$

$Z_i = \ln [-\ln(1 - (i-1)/(n+0.25))]$

Here $[r/2]$ is the integer part of the number $r/2$.

If $M > F_{\text{crit}}$ the H_1 is accepted.

Number of test (n) = 11

Number of failure (r) = 11 $K_1 = 5, K_2 = 5$

So the Mann's test Statistic is

$$M = 5 * 3.45531 / 3.91143 * 5 = 0.8833$$

Number of degree of freedom for numerator

$$2 * K_2 = 2 * 5 = 10$$

Number of degree of freedom for denominator

$$2 * K_1 = 2 * 5 = 10$$

Now the value of F_{crit} may be obtained from F- distribution
 $F_{\text{crit}} = 2.97$ (from F- distribution table)

$$M < F_{\text{crit}}$$

Thus Hypothesis H_0 is accepted which says that the failure times come from Weibull distribution. (Similarly MLE estimation and Mann's Test are conducted for all the machines.)

3.1.2. Over All Reliability of System.

The over all reliability of the system is calculated as per the series combination of various machines. $R_{\text{sys}}(t) = R_L(t) * R_M(t) * R_{\text{HB}}(t) = 0.8343 * 0.9742 * 0.9288 = 0.748$

3.2. Cycle Service Level

From records it was found that from last two years unit send twenty two deliveries to a particular company. Out of that about 12 were found to be in the quoted supply time rest were late. With this information CSL can be estimated as $\text{CSL} = 12 / 22 = 0.55 = 55\%$

With such a small value of service level safety stock could be very high it is estimated later on.

3.2.1 Standard Deviation in Supply Lead Time

From records various supply lead times are takes as (in weeks)

21, 30, 21, 19, 18, 14, 11, 36, 39, 23, 11, 20, 19, 19, 22, 17, 16, 19, 23, 28, 27, 15

With this data avg value of supply lead time is 21.27 weeks
And Std. Deviation in supply lead time $S_L = 7.15$ weeks

3.2.2 Effect of CSL and Standard Deviation of Supply Lead Time on Safety Inventory

TABLE-1

Avg demand per period D(assumed)	Avg Lead Time	Std Deviation in Demand per period	Std Deviation in Supply Lead Time	Safety stock during lead time D.L	Std Deviation in demand during lead time $\sigma_L = (L \cdot \sigma_D^2 + D^2 \cdot S_L^2)^{0.5}$	Extra Safety stock For supply time deviation $SI = ES^{-1}(CSL) \cdot \sigma_L$
1000	21.3	150	7.15	21250	7133	900

In above table it is shown buyer has to make a very large safety inventory due to large value of supply lead time moreover it is further required to keep extra inventory for deviation in supply time.

4. SUGGESTIONS TO IMPROVE ACCEPTIBILITY OF SMALL SUPPLIER IN SUPPLY CHAIN

- Proper preventive maintenance plans are required as the machines are old and lying in wear out zone. This will help to reduce supply lead time and improve quality of product.
- Increasing number of machines (redundancy) can also improve the reliability and can reduce the supply lead time.
- A comprehensive RAM Analysis followed by FMECA Analysis can help to identify and mitigate the various causes of failures and poor performance.
- A proper training to the employer and employee can induce competency up to some extent.

5. CONCLUSION

Statistical investigation of performance data indicates the various critical issues of the system and its effects on the performance of the supply chain. Because of frequent

failures, break downs and obsolesces of machines the operation reliability of the system is very low about 0.74 which can be further lowered if all machines and equipment will be considered. Due to lower operational reliability company could not supply the items in shorter supply time which ends up with a high level of safety inventory for buyer and the situation becomes worst when it could not meet the supply lead time which it quotes to its buyer as it forced the buyer to keep extra safety inventory to cope with supply time deviation. But the buyer never wants to keep its safety inventory level high as it reduces its profit margin and over all supply chain profitability. Due to above reasons these suppliers struggle and ultimately moved out from the supply chain. If small supplier could get sufficient support from the bigger players and academia it could survive and effectively participate in supply chains to exploit the globalization.

Integrated Approach for Job Scheduling in a Production System

Ankur Josh¹, Rohit Kumar Sahu², Girish Thakar³

^{1,2,3}Industrial and Production Engineering

Shri G. S. Institute Technology and Science Indore, Madhya Pradesh, India

Abstract: When a large number of jobs and machines are taken into consideration, efficiency in job shop scheduling plays a vital role. As the number of jobs & machines increase, the job shop scheduling problems approaches to a higher difficulty level. Many heuristic methods are devised that produce solutions with near optimal solution. This work deals with the job shop sequence using an algorithm aimed at creating a simulated model. The input parameters are the demand, work in progress inventory. The current paper emphasis on optimization of a production line with an objective to reduce the makespan and increase the utilization of machine.

Keyword: Jobscheduling, Makespan, MachineUtilization, Simulation, Optimization.

1. INTRODUCTION

In a manufacturing line, makespan stands for the time of beginning of processing of the first job in the lot to the last job is completed. By improving makespan one can achieve higher production rate, and be able to meet the demand as per or before the dates. Researchers are constantly aiming to reduce the makespan by using different approaches.

The flow shop scheduling model was first developed by Johnson, 1954. Johnson developed an exact algorithm to minimize the makespan for 2- machines flow shop scheduling problems. The flow shop scheduling problem has proved to be NP-hard. Due to the complexity of the problem, it is difficult to develop exact methods to solve this problem. Hence, researchers proposed different heuristics and meta-heuristics to solve the flow shop scheduling problems. The important heuristics were developed by Rajendran and Chaudhri, 1990 and also proposed to solve the flow shop scheduling problems. Akhshabi et al., 2012 proposed a parallel genetic algorithm to minimize the makespan of flow shop scheduling problems. Vince Caraffa, 2001 uses considering the problem of minimizing the makespan of flowshop operating without buffers (intermediate storage) and develops a genetic algorithmic approach to solve large size restricted slowdown flowshop problems of which blocking flowshop problems as a special case.

Review of literature provides motivation to develop and demonstrate a model for optimization using simulated based approach for job shop planning and job scheduling for a multi-component machine. This paper is organized as follows. Section 2 presents the industrial problem description. A section 3 gives detail of the approach and formulation. Section 4 gives the results and graphs. Section

5 concludes the paper and identifies the future scope of work.

2. INDUSTRIAL PROBLEM DESCRIPTIONS

Work done in this paper is based on working of a manufacturing industry AVTEC LTD. Pithampur, M.P, which is a manufacturer of power train and precision-engineered products. Production line producing multiple components is studied where 3 different components are processed on a single machine. The sequence of components to be processed directly affects the make span and make span is related to the production rate and higher cost to the company as well. Also, some what if scenarios are also considered like what if demand of any product increases suddenly then what should be the sequence of components to be processed? Similarly, sequence of components will also lead to change in total machine utilization. Machine utilization is an important factor from the production point of view.

AVTEC LTD has been divided in three sections namely engine plant, transmission and assembly line. The research is conducted in the engine plant specifically on a camshaft line which has 11 machines, each having different operation and cycle time. The camshaft line is chosen because most of the machines are mature and lot of data is available there. The components are manufacture in single lot or batch to eliminate the time lost due to setup change. On the very first machine, 3 different components are processed out of which 1 component is sent to different line for further operations and remaining are forwarded into the same line. First machine is a batch machine so the sequence of operations on components is followed by the operation on the first machine. The process of operation on a component is enlisted in table 4 in a reference. In order to meet the

consumer demand Three shifts are run: A and B are staffed with 8 operators, with the night shift C, is staffed with 2 operators. The bulk of the production is completed by shifts A and B, with C producing a small quantity and being deployed on machines that were disrupted in the other shifts. Available time for a month is 31200min. Along with improper scheduling, production is also affected by the unavailability of raw material by suppliers' end. There are two suppliers for a camshaft line, effect of one supplier is neglected because of its large lead time and data related to lead time is described in table 3. This leads to concentrate on finding proper sequence for optimizing the makespan period and machine utilization.

3. APPROACH

A model of production line is prepared on the simulation software. This model represents the production line considered for this work. All the data are fed to the model like cycle time, machine failure behaviour, inventory (work in process, finished goods), demands, etc. are collected from manufacturing industry. Some basic logics of coding like IF- ELSE logic and some pre-defined keywords existing in software are used. Also total Work in progress (WIP) inventory were constrained as:-

For product 1
 $WIP \leq 230$

For Product 2
 $WIP \leq 60$

All the variable data can be fed through MS-Excel, and result can be obtained in any form either MS excel or other software.

Each optimization problem should have an objective function that has to be either minimized or maximized in order to obtain a certain solution. In this case, the objective function is the value of makespan and the total machine utilization. The span value can be defined as follows

MAKESPAN

$$F(x) = \sum_{i=1}^n CT_i + \sum_{i=1}^n WT_i$$

Where 'CT' represents cycle time,
 'N' represents total number of parts
 'WT' represents time loss due to loading – unloading of parts.

MACHINE UTILIZATION

Machine Utilization can be calculated as –

$$G(x) = 1 - \frac{\sum DT}{\text{Available time}}$$

Where 'DT' denotes downtime

From the above equation makespan and utilization are calculated for different scenarios of sequence to get the optimized result.

4. RESULTS

Various sets of data regarding machine failure behaviour, supplier's lead time, cycle time, demand pattern of different components from past and for many more parameters were obtained. After collecting this information, a detailed analysis is carried out to find some kind of pattern. According to data analysis, machine failure pattern was following Weibull distribution.

And demand variation is shown below: -

Fig. 1. Graph Showing Monthly Variation in Demand

Based on the model, Sequencing for the first machine is considered as major parameter for the above stated objective function. And the results found for different scenarios are depicted below

CASE 1

For regular demand i.e. based on the previous data available, makespan and machine utilization is obtained by varying the job sequence on machine, here 'P' is used to indicate the selected sequence. (Explained in Table1)

CASE 2

When demand of any one product gets double, and demand of other products remains same as previous.

CASE 3

When demands of all components are equal and are higher than the normal demand.

TABLE 1: Sequencing of jobs.

P	Job Sequence
1	Product 1, 2, 3
2	Product 1, 3, 2
3	Product 2, 3, 1
4	Product 2, 1, 3
5	Product 3, 2, 1
6	Product 3, 1, 2

Fig. 2. Graph: MakespanVs Sequence

Fig. 3. Graph: Machine Utilization Vs Sequence

TABLE 2: Makespan and Utilization corresponding to the value of P, when value of η increased by 20%.

P	1	2	3	4	5	6
Makespan (Sec)	10145	54680	20792	23355	57225	60703
Machine Utilization (In %)	4.6	22.6	9.6	8.6	20.4	19.4

TABLE3: Supplier Lead Time

SUPPLIER	Pre-processing time	Post-processing time	Transit time
MAHLE	2 hours	2 hours	2 days
AKAR TOOLS	2 hours	2 hours	4 days

5. CONCLUSION

From the above Graphs and other simulations, one can conclude the following: -

- For any change in the demand, as in case2 and case 3 the sequence that yields minimum MAKESPAN is P=1 i.e. sequence should be Product 1, 2, 3. And for maximum MACHINE UTILIZATION, the sequence is P=2 i.e. Product 1, 3, 2.
- If the Mean Time to Repair is changed by increasing the value of η by 20%, then the sequence remains same and value of MAKESPAN decreases and MACHINE UTILIZATION increases, but on further changes in η value yields the same optimized value.

Computerised Maintenance Management Systems: A Critical Literature Review

Mohit Garg¹, Sarthak Sanjeev², Anurag Lakhara³, P.C. Tewari⁴

Department of Mechanical Engineering
National Institute of Technology, Kurukshetra, Haryana, India

Abstract: Computerized Maintenance Management Systems (CMMS), also known as Enterprise Asset Management (EAM) is an essential operational and management tool for managing asset preservation, ensuring that production systems operate as required thereby minimizing downtime. The Purpose of a CMMS is to manage, capture, track inspection, maintenance and repair activities of an organization. It provides a scheduling facility for maintenance for planned preventive work on maintainable assets. CMMS can eliminate manual data entry, incorporate alerts and shift focus from unnecessary administrative tasks to performing maintenance activities. These systems not only allow the maintenance groups to save time with calibrations and record keeping, but also check on field device performance online. As an added benefit system such as these are allowing maintenance groups to move from a reactive to predictive approach in their daily activities. CMMS helps in improving inventory control, work order generation, asset management, safety, regulatory compliance, real-time reporting, lower overhead, reducing the amount of time when machines are not in use, killing downtime in effect. CMMS solutions can be found in almost every industry because they bring to the table substantial organization, maintenance planning, control of maintenance and cost savings. CMMS users include facility and maintenance management, asset planners as well as maintenance staff.

Keywords: CMMS, EAM, JMAR, RCM, GIS.

1. INTRODUCTION

1.1 MAINTENANCE

Actions necessary for retaining or restoring a piece of equipment, machine, or system to the specified operable condition to achieve its maximum useful life. Maintenance comprises of concepts for the optimization of equipment, procedures, and departmental budgets to achieve better maintainability, reliability and availability of equipment. Maintenance involves keeping the workplace, its structures, equipment, machines, furniture and facilities in good repair and operating efficiently and safely. It includes many tasks like repairing, replacing, servicing, inspecting and testing. The term could also be used in relation to the importance of keeping your staff safe, fit and healthy. Maintenance can also be classified as Planned Maintenance (Corrective, Predictive, Preventive) and Unplanned Maintenance.

1.2 CMMS

CMMS is a computerized system designed to enhance efficiency and effectiveness of maintenance activities typical features include planning, scheduling and monitoring of work orders and maintenance needs. It maintains a computer database of information about maintenance operations. It helps for quickly and efficiently deciding, planning and organizing various jobs for effective maintenance. Before applying CMMS, various factors

should be taken into considerations like reduced cost, better organizational methods, reduced paper work and improved communications. CMMS can be applied in various areas like Manufacturing, Federal, State and Local governments, Property Management, Hotels and Resorts, Energy Plants, Oil, Gas and Mining, Hospitals and Clinics, Schools and Universities

2. LITERATURE REVIEW

2.1 Application of Modern Computerized Maintenance System

This paper brings the attention to the considerable effects of computerized maintenance systems upon the overall production economies; the implementation of maintenance systems potentially leads to the reduction of production costs by 10-15% and increase of utilization of production capacities in the range of 15-30%. Such results are rather difficult to achieve using even the most sophisticated production control and planning/ scheduling algorithms developed with great effort.

A case study of the development and implementation of the Czechoslovak UNDP/UNIDO project "Application of Modern Computerized Maintenance System" is given, Co-ordination of production and maintenance plans by the use of computerized data base, including spare parts manufacture and inventory control, further contributes to the overall maintenance and production economies. This

paper describes a computerized maintenance system project that has proven these results in the field of metallurgical production in Czechoslovakia. The implementation of such systems in other countries has shown similar experience. (Krouzek 1987)

2.2 Database Technology and the GIS Field Program

This paper discussed the database technology and the GIS field program to maximise the life of wood poles that supports the electrical transmission lines. In database technology, automated mapping process is time consuming and manpower intensive process that often yields less than satisfactory results, so the global positioning system is a reliable tool for positioning the wood poles. GPS combined with quality attribute collection in the field, provides a product that will sustain future mobile computing application. New technology makes data gathering in the field lower in cost and more accurate. More accurate data leads to good management and decision making of field and attachment inventory. (Bingel et al. 1998)

2.3 CMMS as Database / Calibrator System

The author categorizes CMMS in two types-database/calibrator system, database/calibrator/online system. Both systems use a computer, a database and a handheld calibrator. The main difference is that the second one consists of smart field devices (that are equipped with microprocessor), a communication protocol and software which can reside in a personal computer. The system represents the information and calculation in a consistent format. In this fashion maintenance personnel can be automatically and instantly notified of a device needing maintenance. (Medlin. 1999)

2.4 Challenges and Implementation Process

After successful implementation of CMMS in Chelan County PUD, author explains challenges and implementation process. CMMS provide a large database and the analysis tools to improvements based on recorded history. Requirement for implementing CMMS are: Training of workers, Collaboration of supervisors and managers with craftsmen and a dedicated and focused CMMS project team. These systems also provide users with one program that support a multitude of functions other than maintenance.(Blackmore 2001)

2.5 Development of JMAR

The author discusses on ongoing medical informatics and business process reengineering research project. The paper focuses on JMAR (Joint Medical Asset Repository) used by US military service. JMAR was originally envisioned to correct medical supply and drug distribution problems that occurred during operation desert storm. This paper discusses the history and development of JMAR from 1997

JMAR is a critical component of the joint vision 2020 plan is an aggressive and all-encompassing one, and it seems well be ahead of civilian efforts found in the literature to date.(Sloane et al. 2003)

2.6 CMMS in Power Systems

For power systems there are usually millions of maintenances intensive equipment's whose reliability is important for power system security and safety. Inthe given paper author has introducedCMMS and recommended to deal with this problem. The paper also discusses the general information-processing model proposed by Hassanain in order to implement the CMMS successfully. This general model consists office sequential management processes:(1) Identify Asset, (2) Identify Performance Requirements, (3) Assess Performance, (4) Plan Maintenance, (5) Manage Maintenance Operations. Successful CMMS is expected to help electric utilities manage resources effectively andimprove utilities' efficiency considerably.(Zbihong et al.2005)

2.7CMMS for Military and Medical Sector Uses

The author designed and implemented a CMMS to be used at the Chilean Naval Hospital Biomedical Engineering Department. It is designed to meet the specific needs of this military facility and follows the Generic Clinical Engineering Maintenance Management System suggested by Association for the Advancement of Medical Instrumentation (AAMI). (Acevedo et al. 2005)

2.8CMMS Supported by GIS

In the developing country like Indonesia to reach a high reliability index is still very difficult. Yogyakarta province as a part of Indonesia, the electric power supply is managed by Yogyakarta electric power distribution region that serve more than 650, 000 customers and supported by more than 11, 000 power distribution transformers.The CMMS is developed on based of digitalizing distribution line networks, customers' connection, inventory of the assets, and man power.

This CMMS also supported by GIS in conjunction with the reduction of the time needed to restore the system during fault. The first stage is the development of the Geographical Information System application. The second stage that must be carried out is the integration between the application of the customer service, payment system and power failure services. The integration of these elements will make the system able for real-time monitoring working. (Tumiran 2008)

2.9 CMMIS for a Tyre Manufacturing Process Industry

The author developed CMMIS for a tyre manufacturing process industry. He described drawbacks and advantages of CMMIS. Modules used by author are equipment menu,

work order process menu, preventive maintenance menu and spare part details. These modules and sub modules provide all the information that a maintenance manager need and also provide a good data base for day to day decision making, in long term planning, reduction in downtime, reduction in maintenance cost and inventory cost and increased productivity, etc.(Ramachandra 2012)

2.10 CMMS For Medical Devices by Prioritising it Bases on its Effect

The author designed a CMMS for medical devices CMMS for medical devices in Royal Medical Services. The effective maintenance management of medical technology influences the quality of care delivered and the profitability of healthcare facilities. The existing system for maintenance was studied and a need for change was observed. Traditionally the maintenance was carried out on 'First come first serve basis.' The suggestion was made to prioritise the maintenance of devices based on their effects on the patients due to their failure. The five steps of maintenance (Notification, Assignment, Job-in-progress, Closure and Reporting) were integrated into the existing system.(Fouad et al. 2012)

2.11 Development of CMMS for Storage and Accessible by LAN

The author discussed the design, development, and Implementation of maintenance software for RDCIS, SAIL. The civil and electrical maintenance activities were outsourced to contract parties, that were selected through open Tender enquiry basis. The existing software had a limited scope, running on a standalone personal computer supporting only one application user. It did not have the provision to keep the history of previous year records. There were no separate soft wares for Civil and Electrical maintenance. The Implemented CMMS software: The project comprised of database design, application design and development of software for storage and retrieval of the scanned documents through user friendly interfaces, The CMMS software was implemented on web based 3-tier technology. The application can be accessed on LAN using the clients like Internet Explorer, Firefox, Chrome, etc. by giving the URL address for CMMS, the middle tier being Oracle application server and the Backend as Oracle database (record keeping). The author implemented the software comprising of five basic modules separating the civil and electrical maintenance for RDCIS Lab complex and SAIL Township and a Complaint lodging system.(Selvi et al. 2013)

2.12 Reliability Centred Maintenance in Gas Company

The author described the development and implementation of CMMS for National Iranian Gas Company. Maintenance strategy used for CMMS is Reliability centred maintenance(RCM). CMMS must be designed for

balancing the maintenance activities. CMMS should minimise the frequency of reactive maintenance as much as possible. For decision making about the priorities for through investigation, the work orders must go through a comparison process. CMMS must be launched from the beginning of the equipment life cycle. The final target of CMMS is identifying the essential events, items and work orders in terms of unit availability, reliability, quality control and maintenance cost, processing in a systematic way. It is suggested to do the survey about effectiveness of this model on plant life cycle.(Beni et al. 2014)

2.13 Reasons behind the Low Success Rate in Implementation of CMMS

The business in large industries greatly depends upon management of maintenance and has a significant impact on profits. Managing this process effectively without computer-based support is almost impossible. It is very common that there is a low success rate among even large organizations worldwide in implementing an effective CMMS to support improved reliability and performance. This paper focuses on understanding the reasons behind the low success rate in implementation of CMMS (6 key reasons) using "Iceberg Model". Author discusses the essential elements that must be included to ensure a disciplined and well-resourced program that can deliver success.(Wienker et al. 2015)

2.14 Multi-Attribute Decision-Making Methodology

He explained need for Computerized Maintenance Management System's decision analysis capability to achieve world class status in maintenance management. Investigations indicate that decision analysis capability is often missing in existing CMMSs and collected data in the systems are not completely utilized. This paper aims to assess and select the most efficient maintenance policies (like BM, TPM, CBM, SLU, DOM, RBM, TBM etc.) to add value to collected data. The analysis has been executed in Case study for manufacturing site in Sweden, to provide new CMMS by adopting a multi-attribute decision-making methodology, namely DMG (Decision making grid), TOPSIS (The Technique for Order of Preference by Similarity to Ideal Solution) and K-means clustering. (Rastegari et al. 2016)

2.15 Identification of Requirements and Various New Features

He discussed the Requirements specification of a CMMS for changeable, agile, reconfigurable and Virtual Production. He aims to develop a CMMS involving the identification of requirements and the specifications of the system, are described in detail, showing the approach that was followed and reflecting about its effectiveness and efficiency. In this various proposed future improvement in CMMS are discussed with the weaknesses & limitations of

currently available systems. He introduced various new features in Maintenance planning, Maintenance scheduling, Performance measurement and improvement and Spare parts management. (Lopes et al. 2016)

2.16 CMMS for a National Thermal Power Plant

Author explained a general framework of CMMS for a National Thermal Power Plant. Currently, it is very difficult to maintain data in written form as it makes much difficult for retrieval of data. Using software for this purpose leads to efficient planning of maintenance aspects. CMMS leads to effective planning, controlling and scheduling of maintenance activities. Various modules such as Equipment, Work Order, Spare Parts, Tools & Tackles, Staff Details, Task Allotment and Safety Records are used. Author also gave general guidelines for creating a CMMS software. (Yadav et al. 2017)

3. CONCLUDING REMARKS AND FUTURE SCOPE

The paper includes various literature reviews of the research done in the field of CMMS for several Production and service sectors. CMMS being an essential operational and management tool for minimising downtime and reducing the overall production cost by increasing utilisation of production capacities. CMMS is part of Enterprise resource planning, is planning and controlling tool which aids the maintenance of enterprise by managing the operation/activities in the best possible way. It focuses on improving various maintenance policies like BM, TPM, CBM, SLU, DOM, RBM etc which helps in increasing the effectiveness of maintenance and focus on maintenance activities. The database maintained by the CMMS software offers easy record keeping, security (that makes tampering with the information practically impossible.) and aiding the maintenance staff by providing previous maintenance exercises. A Properly utilised CMMS can assure management of properly maintaining capital investments on costly plant equipment. CMMS process should be planned and shared. NO SURPRISES. Let the user know what you are doing and get their input. The fear factor is very high in activity based systems. No one has ever been “watched” this closely before.

CMMS can be applied in various areas like Manufacturing, Federal, State and Local governments, Property Management, Hotels and Resorts, Energy Plants, Oil, Gas and Mining, Hospitals and Clinics, Schools and Universities etc.

Identification and Ranking of Factors Affecting Facility Location: A ‘Make in India’ Challenge

Milind Sakhardande, Rajesh Prabhu Gaonkar

Department of Mechanical Engineering, Goa College of Engineering, Goa, India

Abstract: While deciding on Location Selection, the factors that enhance supply chain performance should be considered on prime basis. Presently, the Make in India initiative is aimed at luring investors all over the world to invest in our country. But looking back at a few issues like the Tata Singur plant, it is advisable that we have a proper framework ready for the investors that can guide them in locating facilities in India. Various dormant qualitative factors can surface at the time of finalization of facility location. Many a times, even after the location is finalized and facilities are built, these factors lead to closure of work in advanced stages that might cause huge losses to the business houses. This paper aims at assessing various existing and new qualitative and quantitative factors for location selection in developing countries and prioritizing them over each other.

Keywords: Facility Location, PESTLE Analysis, Supply Chain Performance Measures, Ranking by Paired Comparison.

1. INTRODUCTION

With businesses spreading all across globe, the countries worldwide are opening their boundaries inviting others for setting up plants. The major decisions in setting up businesses take place during the strategic phase. In this phase strategic decisions like type of facility, role of facility and location of facility have to be taken [M.T. Melo, 2009]. The facility location decision making has to be a long term strategic decision. The traditional methods of facility location are based on of minimizing the transportation costs based on suppliers and market locations [D. A. Schilling, 1993; Farahan, 2012]. Over the years, other quantitative factors and qualitative factors [Kalantari, 2013] have also been looked upon during Facility Location Selection. In recent research, qualitative factors have also been combined with quantitative factors [Dogan, 2014] for identifying a facility location.

As per the UN Industrial report, 2016, short term actions may produce quick and lucrative results, but the long-term consequences can be disastrous. Developed countries like United States, Germany and Japan have kept their positions in industrial competitiveness over the long term. These countries enjoy higher, and more sustainable, industrial performance. Such countries have strong industrial policies to back the industrial growth. India may rejoice that it is overtaking China as the world's fastest growing major economy, but the scenario looks more complicated than that. In one of the recent article in Hindustan Times, Five major challenges that loom for our Honorable PM's mission are funds, technology advancement, union issues, availability of skilled labour and overhaul of R & D in India [Narayan]. In one of the recent blog 'the benefits and challenges of manufacturing in India, Jessica Hoyt has identified power availability, cost and fragmentation of

transportation and logistics, labour productivity and intellectual property and protection and enforcement as the major challenges. The developing countries which usually have no firm policies have a lot of dynamic qualitative factors that may surface at the time of beginning of operations in the facility and are subjected to serious consequences that may include closure of the facility as seen in some of the recent cases. The paper aims at identifying such dormant qualitative factors, combining them with other qualitative and quantitative factors. Further, ranking of the factors is done to access their importance by using Ranking by Paired Comparison Method [Paul Newton, 2014].

2. PROBLEM ON HAND

With new initiatives, come challenges. The Make in India initiative of the Government will also have lot of challenges as India is still a Developing country. Over the past, we have seen that a lot of dormant qualitative factors like Political System [Michael, 1993], Maturity of political leadership, blind belief in leadership, Bureaucratic hurdles, Unstable neighborhood, Internal turbulence, internal threats [Sukanta, 2010], Roll of parallel economy [Thi, 2016], health impact [Yossi, 2013] that are vague in nature, predominantly seen in developing countries have not been considered in facility location decisions. Such dormant qualitative factors prevail come to surface when optimal location of the plant is already decided and can eventually turn out to be vital adversely affecting the decisions made and forcing relocation of plant. This has been evident from the past cases like Tata Singur plant shifting to Gujarat [Saibal Bishnu] and Nylon 66 plant moving out of Goa. Hence these factors have to be considered for facility location decisions.

3. METHODOLOGY

A gathering of individuals from industry and the scholarly world brought about distinguishing some dormant qualitative variables that can make issues subsequent to settling the location as found in many of the cases in later past through a group discussion. Political System existing in the nation has a noteworthy part to play in industrialization. This has been considered as one of the variables that can influence location choices. At whatever point a political framework emerges, leaders rise. The basic leadership towards modern development relies upon the matured initiatives taken by the leaders and hence the Maturity of political leadership has additionally been considered as one of the variables. In developing nations, in a large number of the individuals indiscriminately follow their leaders. Hence blind belief in leadership likewise happens to be one of the main considerations that can influence Location choices. Bureaucracy is one more major issue that was considered during brainstorming and many a times as an investor in business you may have a lot of bureaucratic hurdles during the initial phase. For any industry to progress, the area in which it is supposed to be located should have stable neighborhood. In recent past, some of the countries have been facing a lot of internal turbulence and have lots of internal threats, hence these factors have also been considered.

Parallel economy assumes a noteworthy part in numerous nations. In a few nations, whole business may keep running on parallel economy and it gravely influences the development. Role of Parallel economy is additionally enrolled as a likely factor to be looked after. All such factors can create issues even after finalizing the location as seen in some of the cases in recent past hence the authors feel that such factors should be considered along with the existing factors available in literature to develop the framework [Milind, 2017]. In a few nations like India Vastu-Shastra is picking up significance as of late [Edward J. Jaselski, 2015] and has likewise been considered as one of the factor influencing facility location. Supply chains can be disturbed during disasters having a huge financial and operational effect on firms [Trevor et al., 2005]. The location with high Disaster dangers will be never the principal decision for plant setup as the whole business can be damned. Henceforth Disaster Risks likewise must be considered during facility Location Selection. The Factors identified are organized as per PESTLE tool. As the factors are large in number, an alternative to Ranking by paired Comparison method has been devised and is used to rank the factors.

4. PESTLE

PESTLE stands for - Political, Economic, Sociological, Technological, Legal, and Environmental. The term PESTLE has been used regularly to help making decisions

and plan for future events looking at the Political, Economic, Sociological, Technological, Legal, and Environmental factors. An organization on its own cannot affect the factors, nor can these factors openly affect the profitability of an organization. But by understanding these environments, it is possible to take the advantage to maximize the opportunities and minimize the threats to the organization while taking facility location decisions. The various factors affecting Facility Location are classified in terms of Strategic and operational factors using PESTLE tool and are as shown in sub-sections [Milind, 2017]. The factors considered are further sub divided into Qualitative and Quantitative of Static and Dynamic nature. The Political factors recognized from previous research and brainstorming are political system, political stability, maturity of political leadership, threats to the state, unstable neighborhood, Bureaucratic hurdles and government intervention. All these factors are of qualitative nature. Out of all these factors the Political System is considered as static but rest all are considered having Dynamic nature. The static quantitative factors in Economic factors category will be land cost, transportation costs, construction cost, sales & marketing costs and average salaries paid.

The Static Qualitative factors identified as Economic factors are scope for expansion opportunities, competition, impact of present industry status, market characteristics, supplier characteristics, financial incentives, tax structure, currency strength against dollar, economic standing of the country and inflation trend. Role of parallel economy shall be considered as Dynamic Qualitative factor. The Social Factors considered are GDP & per capita income which is of Quantitative and considered to be static. Knowledge base, medical facilities, education system and avenues, Labour characteristics, motivation and enthusiasm of employees, employability, union flexibility, social ethos, linguistic barriers, affect on health of people due to industries, use of vastushastra, impact of religious beliefs on industrial growth, standard of living are static qualitative factors whereas blind belief in leadership, internal turbulence and consumer characteristics are of dynamic nature. The operational Static qualitative factors considered are employee integrity and employee ethics whereas health hazards will be of dynamic nature. In Technological factors, Technology costs and I.T. operational costs are considered as Static Quantitative factors. Energy alternatives & backup, uninterrupted power, labor skill, infrastructure availability, availability of transportation (land/sea/ports) and availability of utilities are of static qualitative nature. In Legal factors, Government Policies and Government Laws & Regulations are considered as Static qualitative factors. In Environmental Factors, factors like Climatic conditions, water availability and impact of industrialization on environment are considered as qualitative factors of static nature and Disaster Risk is considered as qualitative factor of Dynamic nature.

5. RANKING OF FACTORS

Google forms were designed for ranking of factors (importance in locating a facility). The target survey group consisted of Industries /Businessman, Govt. Bodies, NGOs and University Teachers/Residents. The respondents were

asked to input their responses in a scale of 1 to 10 i. e. 1 for lowest influence and 10 for highest influence as shown in sample Table 1. The final value of each factor is based on average of all responses which shows the influence importance.

TABLE 1: Sample Responses

Respondent	Government policies for industry	Govt. Laws and regulations	Political system	Scope for expansion opportunities for industries	Industry competitive scenario	Impact of present industry status
1	10	10	8	10	7	7
2	8	7	6	8	10	10
3	8	7	7	7	7	6
4	8	8	7	9	8	8

6. PROPOSED METHOD FOR RANKING OF FACTORS

The commonly used method of Ranking by paired comparison [D.H. Stamatis] gives results that may lead to similar scores when we have more factors to be considered. This is evident from the fact that the method uses only three numbers i. e. 1 for small difference, 2 for medium difference and 3 for major difference. Further, the method works well with maximum of 15 factors. In the present context, 57 factors are taken into consideration. Hence authors have devised an alternative which takes into account qualitative assessment of target survey group that can counter the disadvantage of the traditional method. From the responses of various stakeholders, the final values of influence importance (IIVs) are calculated as shown in

Table 2. In the next step a matrix of all the factors is formed. In the given matrix, differences between scores are mentioned. If Factor A in the horizontal column is superior to Factor B in the vertical column, then positive difference is mentioned in the corresponding cell pertaining to both and if Factor A in the horizontal column is inferior to Factor B in the vertical column, then negative difference is mentioned in the corresponding cell pertaining to both as shown in sample calculations of Table 3. Then sum of all positive differences pertaining to Factors in the row is calculated. Similarly Sum of all negative differences pertaining to the Factors in the columns is calculated. Finally the negative sums are added as numbers to positive sums as shown in Sample calculations in Table 4 to get final scores and ranking is done based descending scores of factors as shown in Table 5.

TABLE 2: Influence Importance Values (IIVs)

FACTOR	IIV	FACTOR	IIV
Government policies for industry	8.30769231	Power supply	8.5384615
Govt. Laws and regulations	8.46153846	Alternate energy sources and backup	6.4615385
Political system	7.30769231	Infrastructure availability	8.3076923
Scope for expansion opportunities for industries	7.61538462	Availability of transportation facility (road/rail/ports/air)	9.0000000
Industry competitive scenario	7.61538462	Availability of utility services (assistance to main services)	7.6923077
Impact of present industry status	6.92307692	Climatic conditions	7.3846154
Market characteristics (customer proximity/purchasing power)	7.84615385	Water availability	8.0000000
Supplier characteristics (quality/reliability)	7.76923077	Impact of industrialization on environment	7.9230769
Financial incentives	7.69230769	Labour skills	7.8461538

FACTOR	IIV	FACTOR	IIV
Tax structure	7.92307692	Political stability	6.8461538
Trend of currency strength against U. S. Dollar	6.15384615	Maturity of political leadership	6.7692308

7. CONCLUSION

In this paper, the various qualitative and quantitative factors affecting Facility Location are identified. An alternative for Ranking by paired comparison is devised by the authors and the ranking of factors show the influence of factors affecting location decision in an orderly manner. The findings here, in some way or the other will facilitate the investors in Make in India initiative.

Emerging Trends for Improving the Operational Efficiency of Construction Projects

P. Muralidhar

National Institute of Construction Management and Research, Pune,
Maharashtra, India

Abstract: Project profit and loss can be decided based on the efficient operations of the site. Mismanagement of works in the site leads to so many problems like cost overrun, time overrun, loss of quality, over production, may reduce idle time for employees, loss of good will etc. Hence we need to utilize the production resources effectively to enhance the operational efficiency in the projects. There are several ways to improve the operational efficiency of the project sites, which leads to higher productivity, lower expenses, improving the efficiency of employees. Some project orientated strategies may be implemented in a friendly environment to push the employees for meeting the work targets. Recent days some of the projects are tracked by electronic applications like mobiles, e-apps, cloud software etc. The ultimate goal of current research paper is to identify the trends to improve operational efficiency to lower the costs, without compromising productivity, quality and profit through Information and communication technology (ICT) tools.

Key words: Operational efficiency, productivity, projects, ICT tools, e-apps

1. INTRODUCTION

Construction industry is one of the booming sectors in the India as well as world. It is projected to grow about US\$ 1.7 trillion from 2015 to 2020 as per the construction Intelligence centre(CIC) report. It is very important for any construction project to maximize their operational efficiency by different means to achieve the higher productivity as well as to retain good profit in the project (Cooper et.al., 2000). All the parties involved in this process should be flexible when employing new policies and open to change as workers may respond negatively to any given proposal. There are many of the strategies which aim to make incremental progress to the overall productivity of a project (Goldratt., 1997). When these steps are put in action by a team, they are given the ability to accelerate any given project and lead to far more efficient results that save both time and money. The project manager need to record the productivity levels and time tracking may help to identify the actual problems (Kotnour., 2000). Breaking down the larger construction works into individual parts can provide insight into how productive a given worker or team may be. Analyzing and studying elements of the entire project enables construction companies to figure out what changes need to be done (Klastorin, 2004). Time tracking provides a clearer picture in terms of how workers are managing their time, creating opportunities for boosting operational efficiency (Pich et. al., 2002). Currently some of the project managers are tracking the progress of projects by adopting latest technologies by communication through mobile devices which ensures that all members of a construction project can connect with each other both on and off site (V Ahuja

et. al., 2009). Instant messaging apps and various other communication tools can be beneficial for construction companies, saving time and eliminating the need for face-to-face interaction which is, often time-consuming. If an effective mobile app or software is implemented, operational efficiency is boosted and reduces unnecessary delays and interruptions. Similarly cloud and construction software technologies provide a myriad of functionalities are quite helpful for higher operational efficiency (Onyegiri and Nwachukwu, 2011). Generation of e-apps for the projects may integrate the project activities and project stake holders effectively. These e-apps are helpful for better keep track of the overall productivity of a given jobsite. By being more in tune with the details of a specific project, opportunities for adjustment and modification may present itself, which may stand to increase operational efficiency in all areas of the project (Smith: 2007)

2. DEVELOPMENT OF PROJECT MANAGEMENT

The project management was shaped significantly after inventing the Gantt chart by Henry L. Gantt (1861-1919). The Gantt chart helps to track the progress of tasks and the allocation of resources to them over time, and is the central tool for visualizing project progress when using project management software (Goh, J. & Hall, N.G. 2012). In the late 1950s DuPont Company developed the critical path method (CPM). This method plans projects without considering either resources or uncertainty in task times. CPM permits the use of a simple algorithm that delivers optimal solutions. Several project management software packages, including the market leader Microsoft Project

(MSP), also use this method as a key step in developing solutions. The program evaluation review technique (PERT) was developed to find the effect of uncertainty in project. Monte Carlo simulation is used as an alternative to PERT. This methodology avoids the worst problems of PERT. Later critical chain Project Management (Goldratt., 1997) was developed for improved performance of projects. Agile project management became popular tool to have minimal planning and documentation in projects (Wikipedia, 2012).

As per the recent study conducted by the World Bank the scale of complexity has gone up in the construction projects from olden days to present days. Mega value and long duration projects are under stress due to environmental safeguards, infrastructure sustainability etc.. Now a days information and communication technology (ICT) tools are dictating the tempo of our lives and projects (S. Bowden et. al., 2006). Many emergency situations are forcing to implement new trends in project management. Under these situations digital tools are playing a key role to improve the productivity in projects (Peleg B. and Sudhölter., 2003).

3. METHODOLOGY

The information and communication technology (ICT) tools are portrayed significant results in integrating the various activities in projects. The ICT tools cover the usage of computer hard ware, software, communication tools for a specific application. The various ICT tools helpful to address these problems are

- Simple Spreadsheet/Data base Systems
- Commercial Off the -Shelf (COTS)E-tools
- Bespoke Systems
- Enterprise Resource Planning(ERP)

3.1 Simple Spreadsheet/Data base Systems

Any project consists of huge amount of data related to various materials and activities. It is very difficult to manage them in spread sheets, required to store then in proper manner. Spreadsheets cannot handle the same. Also records are required to maintain for the ongoing usage. We need to produce the on demand and scheduled reports. Hence proper data base systems helps to store and retrieve the data related to projects. Spread sheets are used to perform the automatic calculations of available data in the form of charts and graphs.

These are basic tools like MS excel sheets to calculate the cost and time of the project. It involves storing the data related to project and is helpful in retrieving the data. It includes products, orders, base reports, invoices etc. It is created in user friendly manner for easy navigation. Hence it helps an efficient way to enter data, store data, and generate information for invoices, sales by product, sales by

customer, and so on for the projects. Excel spreadsheets helps quickly to calculate what changes in price and sales would do to their revenue by creating various scenarios. They could also use their consumption pattern in excel to analyze trends by generating charts and graphs. This provided an easy way to analyze their data and trends in a tool with understandable and meaningful formats. This information is quite helpful to the supervisor and engineer level in the site. Many project managers applied the same techniques in projects on trail basis to get quicker output from the available data. In most cases, using the combination of a database to store your business records and a spreadsheet to analyze selected information works best.

3.2 Commercial Off the -Shelf (COTS)E-tools

These are experimenting tools developed for business purpose and integrated to existing organization systems. These are excel based tools to calculate the request for proposal (RFP), Standard rate of schedule (SOR) project planning and scheduling systems etc.. These tools are tailored to calculate the cost and time of the project. These tools can be integrated with enterprise resource planning (ERP) software for better results. They are helpful in work estimation, document management system, work measurement system etc. some of the benefits of these tools are accuracy of estimates, quick preparation of bill of quantities(BOQ), accuracy of measurements, improved progress tracking and transparency of payments etc. Some of the e-apps available for tracking the projects are view point, field wire, plangrid, safety meeting app, corecon, iHandy carpenter, Build calc, Construction masterpro, BIMxetc..The integration of various activities in the Commercial Off the -Shelf (COTS)E-tools is shown in the Fig1.

Fig. 1. Integration of various activities in e- tools

3.3 Bespoke Systems

These systems are known for custom made product or service. Currently the project complexity is increasing day by day and expectations are very high, under these circumstances bespoke systems are designed to meet custom specification of small, medium and large scale projects. Bespoke systems proved their significance in business and project applications. The life cycle of bespoke systems is shown in Fig 2.

Fig. 2. Life cycle of bespoke systems

Some of the advantages of bespoke systems are as follows.

- Bespoke systems use software which is specially created and customised for construction projects.

- The customised software can adopt any changes in the construction business and allow you to update the software whenever requirements arise.
- The updates in the bespoke software will enhance productivity and reduce the cost involved in the repetitive data entry.
- Bespoke system helps to consolidate business information against one source.
- It helps to get a greater insight into day-to-day progress of the project with customised reporting and business processing tools.

3.4 Enterprise Resource Planning (ERP)

For any construction project, field staff is very important and their productivity plays a vital role for timely completion of the project. Integration of end-to-end operations reduces the risk and maximises the profitability. The construction project consists of a variety of works and requires a variety of skills. Hence, skills and works are to be integrated in line with the delivery schedule of the project. For this purpose, the application of ERP software in the construction projects.

ERP is the integrated management of core business processes in real time mediated software technology. The business activities include product planning, project planning, managing sales, marketing of products, delivery of services, shipping and payment, finance etc.. So the complete business administration is good in these ERP systems. The various challenges and applications of e-tools in construction projects are portrayed in Table 1.

TABLE 1: Challenges and Solutions

Challenges	Problem faced	Application of e- tool	Functionality to be adopted	Data required
Delays in execution	Lack of master plan. Delays in designs and drawings	Time management systems	Templates for estimation and drawings	Standard rate of schedule (SOR) BoQ validation Document
Improper resource allocation	Poor resource planning	Project management systems	Updation of planning and scheduling	Planned Vs actual progress report
RFI and Poor scope	Lack of standardised contractors	Ms office templates BOQ automation	Collecting the standard data	Design reviews
Communication management	Lack of information collection and sharing	Content management systems(CMS)	Tracking the performance and generating status reports	Milestone reports Financial reports Budget reports
Procurement delays	Faulty choice in contract type Lack of consistency in application of tender rules	e- procurement systems	Online bid submission, evaluation Invoicing the payments	Tender notices, SBD, RFP

Challenges	Problem faced	Application of e- tool	Functionality to be adopted	Data required
Managing project risks	Lack of risk management tools and practices	Risk management systems	Record and quantify the risk occurrences&Predict the risk occurrence	Analysis of risk assessment Generation of reports
Project Integration	Progress is not updated properly	ERP systems	Day to today work updating by concerned in charge	Data from work location

4. CONCLUSIONS

There are multiple approaches that are emerging in the area of project management to improve the operations of the projects. These improvements are helpful from conceiving to the commencement of the projects. The current paper highlights the application of some of upcoming trends and their implementation in construction projects. The application of various e-commerce tools mentioned in the research paper proven significant improvement in operational efficiency in construction projects and other projects as well. The project manager has to realize the benefits and its impact on the project in the long run for better solutions. The new project management approaches provide the tools and environment to plan, monitor, track, and manage schedules, resources, cost and quality. In the paper presented some of the tools have proven to be successful and output gave the satisfactory results during implementation. It serves as benchmark for project manager for future planning as well as good documentation.

During the execution of the projects the proposed e-tools and project oriented apps are to be developed and installed by the concerned project members to get updated details about the project. These updates are uploaded by concerned in-charges of the project to provide updated information to others who are involved in the project from time to time. It helps to monitor and improve the project activities in a better way for improving the operational efficiency.

Reliability Centered Preventive Maintenance for Pressure Relief Valves

Siddharth S. Thambad, Himanshu V. Patel

Department of Mechanical Engineering
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

Abstract: Maintenance in a Pressure Relief Valve plays a key role as it is the last line of defense against overpressure and loss of containment. The interval of maintenance for the pressure relief valves was studied from the date of installation to the last maintenance carried out. This research intends to optimize the preventive maintenance interval by calculating the governing probability of failure based on which the next maintenance interval is decided. Design, maintenance and operating changes resulting from data and failure analysis can provide significant reliability improvements and reduced costs over the lifetime of a valve.

Keywords: Reliability centered maintenance, Preventive maintenance, Probability of Failure, Cost Optimization, Risk based inspection

1. INTRODUCTION

Components and parts of most of the equipment deteriorate due to utilization and could lead to breakdown. Preventive maintenance is used to reduce the rate of unexpected failure which is more economical compared to breakdown failure (National Research Council, 1991). Downtime due to breakdown affects the productive capability of physical assets by reducing output, increasing operating costs and affecting customer service. The effects of downtime are being aggravated by the worldwide move towards just-in-time systems, where reduced stocks of materials throughout the supply chain mean that quite small equipment failures are now increasingly likely to interfere with the operation of an entire facility (Moubray, 1997). The cost of maintenance is rising steadily it is one of the highest cost according to the proportion of expenditure that an industry has to incur.

There are multiple types of maintenance strategies that have been utilized in industry mainly (1) Breakdown/Reactive maintenance (2) Preventive maintenance (3) Proactive maintenance (4) Predictive maintenance (5) Reliability Centered maintenance. Preventive maintenance was put to use so that the breakdown of machine and equipment is prevented. Although preventive maintenance has potential benefits of uninterrupted production there are disadvantages involved such as need of high labor, and huge upfront cost for regular maintenance. For equipment those do not hinder the production rate and the safety of workers and environment do not require the extensive predictive maintenance strategy as it is not cost effective. Therefore, in this case where the equipment is not critical breakdown maintenance ideology is used. For optimal maintenance of a plant the above-mentioned strategies are utilized based on the criticality and the significance of the equipment in the

production process, as an outcome Reliability Centered Maintenance originated. (Vishnu C. R., 2016)

One method for relating reliability to PM is known as Reliability-centered maintenance (RCM). RCM is a qualitative systematic approach to organizing maintenance (Moubray, 1997) (Nowlan & Heap, 1978) (Smith, 1993). It originated in the aviation industry in the 1960s with the introduction of the Boeing 747 series, and the need to lower PM costs in attaining a certain level of reliability. The results were successful and the methodology was developed further. In 1975, the U.S. Department of Commerce defined the concept RCM and declared that it should be used in all major military systems (Nowlan & Heap, 1978).

Reliability centered maintenance is a high-level maintenance strategy that is meant to optimize all the available equipment in the facility. A variety of maintenance approaches are used to put together an overall approach that is conducive for every different system and equipment category. These maintenance strategies are optimized provide most overall efficient functioning of the plant.

The goal of RCM philosophy is to provide the stated function of the facility, with the required reliability and availability at the lowest cost. RCM requires that maintenance decisions be based on maintenance requirements supported by sound technical and economic justification.

Today most of the manufacturing industries relies mainly of automation of the required processes and reduction of manpower generally required. This has led to copious equipment being engaged for functioning of a machinery. Therefore, the reliability of subsystem is extremely important.

If preventive maintenance is being conducted regularly as planned then the unplanned maintenance/repair work hours are reduced. If more preventive maintenance is done then the actual planned repair hours is reduced as well. But if excessive maintenance on an equipment is done then failures can be induced which would be expensive to reform or else excessive money would be spent in over maintaining the equipment which could also be expensive. (Guo, Li, & Wolf, 2016)

Providing spare parts and components under preventive maintenance which can be an effective way to reduce the operating cost, as maintenance and operation are interdependent. (J.Xie & Wang, 2008). Tsai et.al has studied the cost of preventive maintenance components using genetic algorithm (Tsai & K.Wang, 2001). (H.Li, M.Li, Q.Liu, & Li, 2010) proposed an integrated model to balance the preventive maintenance and production scheduling.

The Reliability Centered Maintenance (RCM) applied here for maintenance of pressure relief valve (PRV) thru proper study of Failure Modes and Effect Analysis (FMEA) reliability analysis approach. This analysis identifies the various failure modes affecting PSV, along with the causes and consequences, and the entire system.

2. FAILURE MODE EFFECT ANALYSIS

It is planned to determine and understand the possible failure modes and their causes and the effects of these failures on the system or the user for a given process. It is used to evaluate the risk associated with the identified failure mode its effects and causes, and seek for possible corrective measures of the most serious concerns (Smith J. , 2013).

Fig. 1. FMEA is a ground-up method of preventive quality

assurance (Wirth, Berthold, Krämer, & Peter, 1996). This method does not allow the evaluation of the reliability function of a complex system but it allows to identify and analyze all the system faults, evaluate their importance in the reliability of the system and then focus on maintenance practices and their effect on system reliability. Moreover, FMEA allows to deal with uncertainty due to imprecision associated with the complexity of the systems as well as vagueness of human judgment.

FMEA uses data from the equipment in operation to individualize the more relevant faults of the system without theoretically modelling the cause-effects relationship of failures. The effectiveness stems from the real operation based approach: it allows to select cost-effective actions aimed to correct the maintenance.

Recent studies and findings display a rise in interest of the applications of RCM and FMEA to new fields, such as the petrochemical industry (Kangavari, S. Salimi, & Askarian, 2015), automotive industry (Belu, Ionescu, & Misztal, 2015), electrical engineering industry (M. Bujna, 2014), , pharmaceutical industry (T. Yesmin, 2013).

There are many pressure relief valves in a process industry at different stages of the operation which helps to regulate pressure at the desired value. The FMEA of the Pressure relief valves is important for safe and reliable operations of an entire process plants. In process industry usually, the Pressure relief valves are repaired mostly than replaced, and replaced if it has been subjected to structural damages and in case of non-availability of spares. Therefore, the main FMEA function is to analyzing the failure mode and the likelihood of failure being discovered before occurrence. In this study the general failure modes of Pressure relief valves are being classified into mechanical, calibration and other general failure modes.

Fig. 1. FMEA methodology

3. RISK BASED INSPECTION (RBI)

Risk based inspection process points out, analyses and maps industrial risk (due to various factors) which can compromise equipment capability in pressurized equipment and structural strength. RBI states these risks which can be controlled through thorough analysis and inspection. RBI can state if inspection is needed if additional data and parameters are provided which is targeted towards underlying uncertainties related to the risk about the present and future anticipated damage state of the equipment. RBI should not be utilized to recommend an inspection which does not elucidate the damaged state of the equipment.

In situations where probability of failure is the driving factor RBI should suggest other reduction options like repair, replacement or actions which reduce the risk criteria. RBI is utilized to prioritize inspection related activities, usually noninvasive techniques as audiometer to detect the passing of PRV or process instrumentation (such as pressure recorder of system) to detect the failed to open during overpressure. The plan which results includes the type of scheduling of inspection for an equipment. In addition to Noninvasive examination additional risk mitigation activities identified by an RBI analysis and depending upon the situation may include change in material of construction, installation of corrosion resistant liners, operating condition changes, injection of corrosion inhibitors.

Consistency and repeatability of analysis are critical to produce an effective RBI program, as RBI is based on relative risks. The overall objective of the maintenance process is to increase the profitability of the operation and optimize the total life cycle cost without compromising safety or environmental issues, this principle is in accordance with RCM philosophy. (Overview of Risk-Based Inspection (RBI), n.d.)

4. THE P-F CURVE

The P-F Chart is one of the most important tools for a reliability centered maintenance plan. It displays the relationship between machine breakdown, cost, and how it can be prevented. The same methodology can be used for PRV overhauling and calibration cycle.

As the machine is working producing desirable output today, does not mean that failures are not already beginning to occur within the system. Most of the machines give some sort of warning that they are in the process of occurring or are about to occur. If evidence can be found that something is in the final stages of failure, it may be possible to take action to prevent it from failing completely and/or to avoid the consequences.

Fig. 2. PF Curve

The failure analysis done in the pressure relief valve is based upon the principles of PF curve. Usually the deterioration of the Pressure relief valve is detected at the point P. If it is not detected at point P then the pressure relief valve starts to drastically deteriorate until point F and then fail eventually. Early signals of failure are where the industry needs to focus so that Pressure relief valves can be kept running at full capacity and minimize downtime (Moubray, 1997).

5. CASE STUDY

The main objective of the study is to evaluate the feasibility of increasing the maintenance time of Pressure relief valves. For this purpose, the working, inspection procedures and routine maintenance procedure was studied. Later, probability of failure of various PRVs were determined for their multiple inspection iteration and all the data was compiled. The governing probability of failure was decided according to the calculated probability of failure-failed to open when required & leak. This leads to economic usage of the funds allotted for maintaining the PRVs as calculated number of routinely maintenance ensures prolonged life and safety of PRVs.

These failure criteria have been taken into account by considering the API 581-RBI standards.

5.1 Probability of failure on Demand

The fail to open (FAIL) failure mode is the primary concern since this failure results in the potential of over pressuring protected equipment and loss of containment. Included in this case is the instance when a valve only opens partially (VPO), where consequences are not as severe, but equipment may be over-pressured nonetheless.

API RBI considers data indicating a partially open valve as a failure to open. Data that indicates a valve opened above set pressure (OASP) is included in the fail to open failure mode since the probability of failure curves are based on bench test data where a failure is defined as any test requiring a pressure greater than 1.3 times the set pressure. A test point that opens above set pressure but does not exceed 1.3 times the set pressure is considered a successful test and is not included in the fail to open (FAIL) case.

Consequences associated with the failure to open failure mode include the effects of fires and explosions on personnel and equipment and the exposure of personnel to toxic fluids as a result of loss of containment. A secondary concern is a failure of the PRD to contain the process while operating at normal conditions.

The API RBI methodology groups the remaining three failure modes together into the LEAK category. Leakage past the valve (LPV), spurious or premature opening (SPO) and valves that stuck open (VSO) are failures that will not result in overpressure or loss of containment from the protected equipment, but will result in potential unacceptable leakage from the process system. The consequences of leakage through a PRD can range from a minor nuisance, causing some loss of product, to a more severe consequence resulting in a process shutdown to repair or replace the PRD. If the PRD discharges to atmosphere, additional consequences may be environmental impact and potential for fires, explosions and toxic exposure.

For the procedure of calculation of probability of failure API 581 should be referred thoroughly from pages 1-40 to 1-41.

5.2 Probability of Leak

A secondary concern is a failure of the PRD to contain the process while operating at normal conditions. The API RBI methodology groups the remaining three failure modes together into the LEAK category. Leakage past the valve (LPV), spurious or premature opening (SPO) and valves that stuck open (VSO) are failures that will not result in overpressure or loss of containment from the protected equipment, but will result in potential unacceptable leakage from the process system. The consequences of leakage through a PRD can range from a minor nuisance, causing some loss of product, to a more severe consequence resulting in a process shutdown to repair or replace the PRD. If the PRD discharges to atmosphere, additional consequences may be environmental impact and potential for fires, explosions and toxic exposure.

For the procedure of calculation of probability of failure API 581 should be referred thoroughly from pages 1-42 to 1-43.

6. RECOMMENDATION

The next date of inspection has been recommended according to API 510 standards.

TABLE I: Recommendation of next Inspection Date

SAP TAG NUMBER	LAST INSPECTION DATE	NEXT INSPECTION DATE	REMARKS	GOVERNING PROBABILITY OF FAILURE
PRV1001	May-15	May-19	Frequency could be Increased from 2 years to 4 years	0.622
PRV1002	May-15	May-19	Frequency could be increased from 2 years to 4 years	0.165
PRV1002B	May-15	May-19	Frequency could be increased from 2 years to 4 years	0.605
PRV1003	May-15	May-19	Frequency could be increased from 2 years to 4 years	0.615
PRV1007	May-15	May-19	Frequency could be increased from 2 years to 4 years	0.481
PRV1201A	May-15	May-19	Frequency could be increased from 2 years to 4 years	0.61
PRV1201B	May-16	May-20	Frequency could be increased from 2 years to 4 years	0.424
PRV2001A	May-17	May-21	Frequency could be increased from 2 years to 4 years	0.54
PRV2001B	May-15	May-19	Frequency could be increased from 2 years to 4 years	0.614
PRV2002A	Dec-16	Dec-18	Frequency is to be maintained at 2 years interval	0.9497
PRV2002B	Dec-16	Dec-18	Frequency is to be maintained at 2 years interval	0.786
PRV2003	May-15	May-19	Frequency could be increased from 2 years to 4 years	0.6113
PRV2003B	May-15	May-19	Frequency could be increased from 2 years to 4 years	0.5504
PRV2004A	Dec-15	Dec-19	Frequency could be increased from 2 years to 4 years	0.6282

7. CONCLUSION

Effective RCM approach ensures the desired performance of the system of interest at a low-cost level. This paper has utilized the API risk based inspection Technology in

optimizing the preventive maintenance interval of pressure relief valves.

The only prerequisites that are required for these calculations are the previous dates of inspection so as to understand the time intervals of inspections, set pressures of

the PRVs, operating pressures of the lines at which the PRVs were operated and the pressure at which the PRV popped during the routine maintenance with which the type of failure (Demand & Leak) can be determined. Following the above based procedures, the probability of both the cases can be determined.

Total Productive Maintenance (TPM) for Achieving Overall Equipment Effectiveness (OEE)

R. Bhut, M.D. Vadhvani

Department of Production Engineering
Shantilal Shah Engineering College, Bhavanagar, Gujarat, India

Abstract: TPM is a holistic approach to equipment maintenance that strives to achieve perfect production. - No breakdown, - No small stops or slow running, - No defects

In addition it values a safe working environment: - No accident

To improve the system of maintaining and the integrity of production and quality systems through the machines, equipments, processes and employees in any industry TPM is applicable. OEE is as ratio of fully productive time to planned production time. OEE is a measure to evaluate the productiveness of the a machine or a process area. OEE is for the perfect production. OEE takes into account all losses resulting in a measure of truly productive manufacturing time.

Keywords: total productive maintenance, overall equipment effectiveness

1. INTRODUCTION

All company wants to leading positions in the global market based on very highly effective manufacturing system. Japans style of management is very effective for increasing production. TPM is an activity in which administration to worker involvement is necessary. TPM brought to industry overall equipment effectiveness (OEE) as a measure that combines losses from unplanned downtime, reduced speed, and quality. Due to the TPM activities main six big losses which effect to the overall equipment effectiveness are remove or reduced (breakdowns, set up, minor stoppage, speed, defect and speed decrease). TPM for achieving maximum OEE. Renew and repair equipment condition for running production. Dealing with very complex equipment is needed very expert or experience person. Motivation for team member and worker is very effective for early equipment maintenance and good quality products. When early equipment maintenance is done so chance for breakdown is reduce or remove.

Continues improvement of industry is possible when worker to administration involved in manufacturing. “ I used it, you fixed it” mentality is changed by training and education, when user take observation of own machine then it increased performance and quality of product. The operator and maintainer are trained to identify problems related to OEE and performs root cause analysis in terms to find the losses.

Master plan for maintenance is very important for the industry. For master plan skills, quality, assurance and

schedule is importance steps. PM analysis in p- problem, phenomenon, physical

And m- machine, man, mechanism, material which done in each piece of equipment is very effective for planned maintenance.

2. LITERATURE

The Nippondenso Co. Ltd. is japanes company they implement TPM first time. Japan institute of plant engineers (JIPE) was awarded TPM. The paradigm idealized plants in which equipment overall effectiveness is maximized. In paradigm history of TPM is describe which mainly focused on zero breakdown, zero defect and zero accident concept. Return cost is maximise then investment on equipment cost it is possible through the TPM activities. Continues monitoring techniques implement in industry based on the human five senses. Equipment life increased due to TPM paradigm. High availability, high overall equipment effectiveness, low energy consumption and rare accidents are due to the TPM PARADIGM. Equipment replacement, equipment renovation, preparation for lubrication and equipment assembly is in TPM PARADIGM.

In 1971 TPM seeks the key goals which are (1) maximize OEE, due to increased performance, quality and availability (2) involve all level of management and worker (3) involved operations, material management, maintenance, engineering, and administration in equipment management (4) improve equipment performance through small group activities and team performance. Operator trained for how to identified problems earlier before they become serious.

Delay times are reduced and productivity is increased due to autonomous maintenance. Downtime and cycle time reduced than availability and performance increased. Four stages which are preparation, preliminary implementation, TPM implementation, and stabilized are nakajima suggested for implementation of TPM. TPM policies defined for medium and long range planning. “To reduced losses by eliminating breakdown, defect, and accidents while improving employees mindset”

TPM is not only maintenance, cost reduction program it is permanently improvement and maintains the overall equipment effectiveness through whole organization involvement. A planned-maintenance stop or “pit stop” on the NASCAR circuit in 1950 was near by four minute long. And now it is 17.5 to 22.5 seconds. Now a days that is less than 20 seconds it is increased performance rating.

3. METHODOLOGY

TPM focuses on optimizing planning and scheduling. Availability, performance and yield are other factors that affect productivity. Availability losses arise from breakdowns and change-over, i.e., the situation in which the line is not running when it should be. Performance losses arise from speed losses and small stops or idling or empty positions. Yield losses consist of losses due to rejects and poor startup behavior in the line producing the products. These losses lead to low values of the overall equipment effectiveness (OEE), TPM helps to raise the value of the OEE by supplying a structure to facilitate the assessment of these losses. Application of TPM leads to both shortand long-term improvements. TPM entails having a (i) Linear organizational structure. (ii) Multi-skilled workforce. TPM seeks to boost the setting of aggressive, but attainable, goals for raising the value of the OEE.

4. OEE CALCULATIONS-

Step-1 For the calculation of OEE mainly availability quality rate and performance efficiency is required.

$O. E. E. = \text{Availability} \times \text{Quality rate} \times \text{Performance efficiency}$

Step-2 operation time is calculated by the loading time and unplanned down time.

$\text{Operation time} = \text{Loading time} - \text{Unplanned down time}$

Step-3 availability efficiency calculated by ration of operation time and loading time.

$\text{Availability} = \text{Operation time} / \text{Loading time}$

Step-4 quality rate calculated by input, quality defects and production input.

$\text{Quality rate} = (\text{Input} - \text{Quality defects}) \times 100 / \text{Production Input}$

5. CONCLUSION

Success of TPM depends on various pillars like 5-S, Jishu Hozen, Planned Maintenance, Quality maintenance, Kaizen, Office TPM and Safety, Health & Environment. Overall Equipment Effectiveness has improved from 63% to 79% indicating the improvement in productivity and improvement in quality due to the tpm activities. It is observed that most of the losses are reduced by planned maintenance and autonomous maintenance .training and education is most required for the TPM implementation. Whole TPM activities are effect on availability, quality and performance. Dynamic model of total productive maintenance is implemented due to this for example maintenance department, engineers and operators can jointly work in organization.

Multi-Manned Assembly Line Balancing: Minimization of Workforce, Case Study on an Automobile Plant

Shashank Kumar, Prashanth Gajavelli, Sunil Agrawal

Department of Mechanical Engineering
Indian Institute of Information Technology, Design and Manufacturing, Jabalpur,
Madhya Pradesh, India

Abstract: This paper is mainly focused on optimization of the “number of workers” working on multi-manned assembly line. This will help the industry to fulfill requirement of extra workers in other departments. Binary integer programming method is used to get optimum number of workers. Mathematical formulation of objective function and constraints are coded into Lingo. Branch and Bound algorithm is used on Lingo to solve the problem. The result of case study shows that almost 17% extra workers are working on the line. For an automobile plant this number is huge. It affected the efficiency and space utilization inside the plant. The current research work will motivate other organizations to use the scientific techniques and published works for the optimization of their assembly line and production system. Data for the case study is taken from an automobile plant.

Keywords: Integer programming, Branch and Bound, Multi-manned assembly.

1. INTRODUCTION

Plants producing large size products and having high production volume are generally using multi-manned assembly line (MAL) system. In multi-manned assembly line more than one workers are working on a single workstation and performing different tasks on a single product simultaneously. In order to established multi-manned workstation assembly line system almost every industry are using conventional method (Mastor. A. 1970). In conventional method of assembly line balancing (ALB) every worker is allowed to work on a single workstation. Conventional methods have many basic constraints and assumptions which are very different from real life assembly line. Scientific methods of balancing assembly line is more generalized and realistic which is presented in this paper for minimization of workers.

This paper proposes a case study of an automobile plant ‘XYZ’¹ located in India. Author visited plant to collect data and see the different types of constraints available on existing assembly line. According to observation, mathematical model of assembly line constraints are developed. The developed models are checked with pre-existing standard problem of literature and then applied for case study.

2. LITERATURE REVIEW OF MULTI-MANNED ASSEMBLY LINE

The world can rarely think about function and production without multi-manned assembly line. Every small and big

industries are used to it. Despite the fact it is used every where, its hard to find literature available on multi-manned assembly line problems. In this section literature available on MALBP are discussed in brief. Literature available on multi-manned, straight layout of line and line which produces single products are presented only.

According to available literature on MALBP, Dimitriadis (2006) presented first time these type of workers arrangement on assembly line. In this paper workers are arranged in different group. Each groups are performing different tasks on different workstations. Paper also presented two level heuristic approach. Assignments of tasks to workstations and assignments of tasks to workers are done by these two level heuristic. The methods proposed by researcher results in space utilization improvement while effectiveness of assembly line in terms of number of workers and idle time remain same.

Fattahi et al. (2011) proposed mathematical model and ant-colony algorithm for MALBP. Paper compare the solution of same problem by solving with two different method. Two different methods are mixed-integer programming and developed algorithm. Proposed mathematical model having multi-objective function with minimization of workers and minimization of workstation. It is observed that the developed algorithm gives exact solution for small size problem. For large size problem ant-colony gives feasible solution near by optimum solution. It also shows the results for better space utilization and workers reduction on assembly line.

¹ ‘XYZ’ is changed name of an automobile company

Qin et al. (2011) presented genetic algorithm mixed with heuristic procedure for MALBP for minimizing the number of workers on assembly line. Algorithm uses roulette wheel selection methods for the generation of initial solution. After that it integrated the heuristic and decode the initial solution several time to get final solution. Developed algorithm shows the improvement in system and reduction in workers on assembly line.

Kelleoguz et al. (2014) proposed new constructive genetic algorithm based on heuristic and also presented some new mathematical constraints to make assembly line more generalized. The developed algorithm directly present the solution into Gantt chart form. Solution is compared with ant-colony and exact solution procedure. It is found that developed algorithm performed well in terms of workers reduction. Results in terms of reduction of workstations shows the poor performance.

Roshani et al. (2016) developed simulated annealing algorithm for MALBP. Based on proposed algorithm, two meta-heuristic procedure is developed. Indirect simulated annealing (ISA) and direct simulated annealing (DSA). In this paper the algorithm is used to solve the Type-II problem of assembly line which is minimization of cycle time. It is observed that both ISA and DSA algorithm gives the optimum result for small size problem. Performance of DSA and ISA is also compared in this paper. When authors fixes the number of workers on assembly line performance of DSA is better than ISA and vice versa.

Chen (2017) proposed a hybrid heuristic approach. This approach combines the method of building the initial feasible solution and simulated annealing algorithm. The introduced algorithm are using several parameters. To find the optimum combination of parameters design of experiment (DOE) and taguchi methods are used.

Literature present above and reviewing others part of literature on MALBP, almost all the authors uses heuristic algorithm to solve the assembly line problem. It is very hard to find some paper with real life implimentation of assembly line case study. This develops the gap between research done and real problem of industry. Aim of this paper is to solve real life assembly line problem for minimizing the number of workers working on line and reduce that gap.

3. MATHEMATICAL MODEL OF MULTI-MANNED ASSEMBLY LINE

The proposed mathematical model is developed according to the requirement of the situation present in the plant. Problem is solved for minimization of workers on line, so a single objective function is developed. Apart from basic constraints of multi-manned assembly line, constraints like group working is used. Kim et al. (2009) proposed a mathematical model for two-sided assembly line, which

further modified for multi-manned assembly line by Fattahi et al. (2011), is used and developed here to solve the problem. Constraints (8) and (10) are two new constraints given by Yilmaz (2016).

Indices

i, h : tasks.

j : Stations.

k : Workers.

Parameters and sets

I : Set of task.

J : Set of workstations.

K : Set of workers.

t_i : Task time.

ct : Cycle time.

$P(i)$: Set of immediate predecessor of task i .

$P_a(i)$: Set of all predecessor of task i .

$S(i)$: Set of immediate successors of task i .

$S_a(i)$: Set of all successors of task i .

Decision variables

st_i : Starting time of task i .

x_{ijk} : $\begin{cases} 1, \text{if task } i \text{ is assigned on station } j \text{ to worker } k \\ 0, \text{otherwise} \end{cases}$

w_{jk} : $\begin{cases} 1, \text{if station } j \text{ is assigned to worker } k \\ 0, \text{otherwise} \end{cases}$

ws_{jk} : $\begin{cases} 1, \text{if station } j \text{ is assigned to } k \text{ workers} \\ 0, \text{otherwise} \end{cases}$

y_{ih} : $\begin{cases} 1, \text{if task } i \text{ perform earlier than task } h \text{ by the worker } k \\ 0, \text{otherwise} \end{cases}$

Objective Function

$$\text{Minimize } \sum_{j \in J} \sum_{k \in K} w_{jk} \quad (1)$$

The goal of objective function (1) is to reduce the number of workers by using the constraints given below.

$$\sum_{j \in J} \sum_{k \in K} x_{ijk} = 1, \forall i \in I \quad (2)$$

$$\sum_{j \in J} \sum_{k \in K} j * x_{hjk} \leq \sum_{j \in J} \sum_{k \in K} j * x_{ijk} - 1, \forall i \in I, h \in P(i) \quad (3)$$

$$st_i + t_i \leq ct, \forall i \in I \quad (4)$$

$$st_i - st_h + A * \left(1 - \sum_{k \in K} x_{hjk}\right) + A * \left(1 - \sum_{k \in K} x_{ijk}\right) \geq t_h, \quad (5)$$

$$\forall i \in I, h \in P(i), j \in J \quad (5)$$

$$st_h - st_i + A * (1 - x_{hjk}) + A * (1 - x_{ijk}) + A * (1 - y_{ih}) \geq t_i, \forall i \in I, h \in \{r | r \in I - (P_a(i) \cup S_a(i) \text{ and } i < r), j \in J, k \in K\} \quad (6)$$

$$st_i - st_h + A * (1 - x_{hjk}) + A * (1 - x_{ijk}) + A * y_{ih} \geq t_h, \forall i \in I, h \in \{r | r \in I - (P_a(i) \cup S_a(i) \text{ and } i < r), j \in J, k \in K\} \quad (7)$$

$$\sum_{i \in I} x_{ijk} - m * w_{jk} \leq 0, \forall j \in J, k \in K \quad (8)$$

$$\sum_{i \in I} x_{ijk} - w_{jk} \geq 0, \forall j \in J, k = 1, 2, \dots, M_{max} - 1 \quad (9)$$

$$\sum_{k \in K} k * ws_{jk} - \sum_{k \in K} w_{jk} = 0, \forall j \in J \quad (10)$$

$$\sum_{k \in K} ws_{(j+1)k} \leq \sum_{k \in K} ws_{jk}, j = 1, 2, \dots, J - 1 \quad (11)$$

$$w_{j(k+1)} \leq w_{jk}, \forall j \in J, k = 1, 2, \dots, M_{max} - 1 \quad (12)$$

$$x_{i1jk} - x_{i2jk} = 0, \forall (i1, i2) \in ZP \quad (13)$$

$$x_{i1jk} + x_{i2jk} \leq 1, \forall (i1, i2) \in ZN \quad (14)$$

$$st_i \geq 0, \forall i \in I \quad (15)$$

$$x_{ijk} \in \{0, 1\}, \forall i \in I, j \in J, k \in K \quad (16)$$

$$y_{ih} \in \{0, 1\}, h \in \{r | r \in I - (P_a(i) \cup S_a(i) \text{ and } i < r)\} \quad (17)$$

$$w_{jk} \in \{0, 1\}, \forall j \in J, k \in K \quad (18)$$

Constraints (2) is assignments constraint it makes sure that each task is assign to a single workstation to a single worker. Every assembly line problem have a set of tasks and they are having some sequence to perform them. Constraints (3) ensure that all the tasks follow the sequence and known as precedence constraints. All the stations have fixed amount of time within that time task have to perform. The fixed time is called cycle time, which is taken care by constraints (4). Constraints (2, 3, and 4) are generally present in every assembly line problems. Constraints (5, 6, and 7) are the sequencing constraints. If task (i) is immediate, successor of task (h) and they all are assign on same workstation than constraints (5) become active for every such set of task. When this satisfied, the constraints

(5) reduced to $st_i - st_h \geq t_h$. Constraints (6, 7) are used when there is no precedence relation between tasks. Constraints (6) become active if task (h) is assign earlier than task (i) in other case constraints (7) is active. Constraints (8, 9) control the distribution of worker while aim of constraints (10, 11) is to verify the number of workers used in each station and load the stations in an increasing manner respectively. Constraints (12) control the sequence of worker. Constraints (13, 14) are positive zoning and negative zoning constraints respectively. These ensures that which set of tasks are done togethe. Starting time of each task must be greater than zero is ensure by constraints (15). Constraints (16, 17, and 18) are binary integer variables.

4. CASE STUDY

In this section, a case study is presented to illustrate how research work can be implemented to real life problem and how it improve the system.

4.1 Problem Description and Data Collection

The problem is to study the assembly line of an automobile plant 'XYZ'. The plant is building special type of trucks. Currently assembly plant is working into four sections. Frame section, Stand I section, Stand II section and Stand III section. Every sections have fix number of tasks and that can be done in that section only due to resoucrs available for doing that tasks. Every tasks comparies of many sub-tasks. Deatil of each tasks and sub-tasks are given in Table 1 with their tasks time. Task time is recorded by stop watch. Each task time is recorded three times and average time is taken for solving the problem.

TABLE 1: Details of tasks and sub-task with number of workers

Sections	Major Task	No. of Sub-tasks	No. of workers	Task time(min)
Frame section	A	40	26	44.31
	B*	25		42.7

Sections	Major Task	No. of Sub-tasks	No. of workers	Task time(min)
Stand -I	C	58	51	23.36
	D	3		9.16
	E	17		23.4
	F	3		5.28
	G*	12		6.93
	H	6		9.35
	I	4		34.35
	J	6		7.5
	K	4		4.7
	L	5		3.4
Stand -II	M	4	60	10.55
	N	7		7.6
	O*	5		3.56
	P	5		6.2
	Q*	6		3.98
	R	6		4.85
	S	3		9.95
	T	3		0.71
	U	7		19.13
Stand-III	V	4	49	9
	W	4		5.03
	X	7		13.75
	Y*	10		19.56
	Total	254	186	328.31
*substation				

Fig. 1. Precedence relation among tasks

Fig 1. Shows the precedence realtions amoung various tasks. There are 25 more precedence relation of sub-tasks. Those realtions are not shown because of privacy and policy of assembly plant. As soon in Table 1 every tasks and their sub-tasks must be done together in that sections only. Automobile plant not agree to change the plant layout and design. Only things in author can do that reduced the number of workers used on assembly line with same arrangement of workstations and plant layout.

4.2 Solution Procedure of Case study

All the precedence relations are checked for parallel task using constraints (6, 7). Whereever possible many large tasks are divided into small sub-tasks to reduce to workload on a single workers and to reduce task time. Make the sets of tasks that are bound to done together. Similarly make the sets of tasks that having parallel realtions and sets of tasks that do not have any precedence realtion. These sets are input for Lingo program. There are various assumption under which the case study is carried out.

1. The problem is solved for manual assembly line.
2. The work piece should be placed in a particular position in order to perform a task.

3. Product and resource repositioning time are also not considered.
4. Breakdown time and non-productive time are not considered while solving problem.
5. Problem is solved for single model, straight line layout.

Minimization of workers are carried out in two part. (A) Solve each task precedecnce by considering separate assembly problem and find new task time for each task (B) Minimize the number of workers using all the above developed mathematical constraints. While solving part B use the new tasks time obtained in part A.

5. COMPUTATIONAL RESULT

In this part, computational results are discussed. The case study are done using LINGO16.0 a mathematical programming software. For this 0-1 integer-programming model is developed using LINGO 16.0 with Intel core i5, 3.20 GHz processor and 4GB of RAM. LINGO used branch and bound algorithm to solve the problem.

TABLE 2: Solution of part A and part B

Sections	Major Tasks	Sub-tasks	Number of workers	Total no. of workers in each frame	Task time (sec)
Frame section	A	44	23	38	173
	B*	31	15		190
Stand -I	C	57	10	50	141
	D	4	3		240
	E	17	7		210
	F	3	2		167
	G*	13	4		108
	H	5	3		198
	I	4	12		187.5
	J	7	4		120
	K	5	4		80
	L	5	1		204
Stand -II	M	6	5	33	146
	N	7	5		95
	O*	5	3		75
	P	5	3		150
	Q*	7	6		53

Sections	Major Tasks	Sub-tasks	Number of workers	Total no. of workers in each frame	Task time (sec)
	R	7	5		80
	S	9	4		165
	T	3	2		23
Stand-III	U	12	10	33	120
	V	4	4		135
	W	4	2		152
	X	8	6		150
	Y*	11	11		120
	Total	283		154	
	*Sub-assembly				

As shown in Table 2. Increased number of workers on some stations does not affect the overall performance of assembly line. This is because at last total number of workers are reduced to an optimum amount. In established assembly line the number of workers, working is 186 and in modified assembly line, the number of workers are reduced to 154. The sub-tasks are increased to 283 from 254.

6. CONCLUSION AND FUTURE WORK

A case study of assembly line is proposed in this paper with 25 workstations with 25 sets of workers. Each sets of tasks contains different sub-tasks. Initially total number of workers working on line is 186 which is reduced to 154 after solving the problem. There are reduction of 17% of workers on assembly line. This will increase the space utilization beside the assembly line. Extra workers working on line can be used for others work in other sector of plant. This will also reduced the cost of production. The above result will also attract many company to apply the published research work as per their requirement.

This work may be extended for modification of whole assembly line by reducing the number of workstations and cycle time. Meta-heuristic method can be applied for comparative study of two different solution.

Route Optimization of Fleet of Passenger Transport Vehicles using Bing MapsTM & Excel Solver: A Case Study

Pushkar S. Marathe, Adwait A. Rao, Gaurav Dalvi, Rajesh J. Dhake

Department of Industrial and Production Engineering
Vishwakarma Institute of Technology, Pune, Maharashtra, India

Abstract: This paper presents a solution to real-life vehicle routing problem to an industry specific application with an objective to minimize the total transportation cost using Bing Maps & Excel solver. The expenditure that organizations have to incur for the daily commute of their employees contributes significantly to the company budget. This paper highlights the use of quantitative and analytical techniques to a real-life routing problem. A metaheuristic technique viz., large neighbourhood search (LNS) solves the problem using excel solver and macros, with sufficient number of iterations to gain accuracy. The output after sufficient iterations with the sequence of steps mentioned is used to create a path-to-follow that minimizes the total distance, thereby reducing the total cost of the transportation.

Keywords: Vehicle Routing Problem, Bing MapsTM, Excel Solver, Large Neighbourhood Search, Optimization.

1. INTRODUCTION

Transportation is an essential aspect of any logistics function and accounts to more than 1/3rd of total logistics costs. It may be of raw materials or finished goods, but transportation of employees can be prioritized above the rest as they are the ones who contribute the most to the operations in the company. This calls for creating a path-to-follow which covers all the pickup points from their destination. This forms the basis of vehicle routing problem, introduced by Dantzig and Ramser, 1959.

Vehicle Routing Problem (VRP) is one of the most commonly occurring optimization problems in the field of logistics. One such case of VRP is of transportation of employees from their homes every morning to the company and sending them back every evening with buses. This adds to overheads costs of the company, so it is important to reduce the cost of transportation by finding a path-to-follow which would have the minimum total distance amongst all possible ways. This version of the problem addresses the following considerations:

1. Limited homogeneous fleet of vehicles: the company owns a fleet composed of identical vehicle types;
2. Possibility of vehicles performing multiple trips;
3. For each vehicle, transportation cost per km.

The goal is to minimize the total cost composed of

- i. A fixed cost for using each vehicle,
- ii. A fixed cost per customer visited, and

- iii. A variable vehicle-dependent cost per distance travelled.

Besides minimizing total distribution costs, for managerial reasons the company is also concerned about three other routing indicators, namely,

- i. Minimize total number of routes employed,
- ii. Minimize total distance travelled, and
- iii. Minimize vehicles' idle capacity.

2. VRP SPREADSHEET SOLVER BY MR. GÜNEŞ ERDOĞAN

Mr. Güneş Erdoğan noticed the need for a standard tool that can be used to solve vehicle routing problems easily. He realized that it is indeed possible to construct a standard tool for representing, solving, and visualizing the results of VRPs on the computer. The resulting open-source Excel workbook named VRP Spreadsheet Solver and its user's manual are available for free download at <http://verolog.deis.unibo.it/vrp-spreadsheet-solver>.

This workbook utilizes Bing Maps web service to retrieve coordinate and distance data, and uses a Large Neighbourhood Search algorithm (proposed by P.Shaw in 1997) to provide solutions. It can solve Vehicle Routing Problems with up to 200 customers. VRP Spreadsheet Solver has been used on four continents by multiple small and medium enterprises, and the beneficiaries have reported cost savings of 10% to 20%.

3. THE PROBLEM STATEMENT

This company is situated at Chakan, and the objective of this paper is to find the optimal number of buses and minimize distances travelled from the workplace. The employee data of 317 employees had been recorded to include:

- Name of employee
- Work in the company
- Bus Stop
- Bus Route

The company wanted a vehicle routing solution such that they required the least number of buses to pick up their employees. Employees were given a survey where on the basis of the above four parameters, their responses were recorded. The procedure to go about this problem includes:

- i. Mapping Locations of company and bus stops.
- ii. Calculating Distance to and from each location.
- iii. Decide number of vehicles that are going to be plying.
- iv. Find a solution by deciding which route can be followed.
- v. Populate this on a map if possible for direct use and analysis.

3.1 Constraints in VRPs:

1: Depots – These depots may be located at multiple places throughout the city and hence this factor is also a variable, unless of course in a particular scenario you are given the data that has only one particular depot. The company is considered as a depot.

2: Vehicles – Vehicles form the basis of the problem since it is their routes that we set out to determine in the most optimal manner possible. It is essential also to take into account that these vehicles have maximum times of plying, and down times where they may be at rest or requiring maintenance. All this has to be factored when setting a time frame for the vehicles in the vehicle routing problems. The

company has a homogenous fleet of vehicles having equal seating capacity.

3: Customers – The employees in this case account for the major factor that determines the number of entities that are being plied, or are plied to. In case of a customer or their goods, there can also be variable quantities of goods that are being transported. It is possible that multiple employees can board/unboard at a given bus stop.

4. METHODOLOGY

The methodology that is followed here can be assigned in stages of work. These stages or steps are listed below along with their respective results. The heuristic algorithm that has been used in this research is Large Neighbourhood Search (LNS) metaheuristic which was proposed by Shaw. Most neighbourhood search algorithms explicitly define the neighbourhood. In the LNS metaheuristic, the neighbourhood is defined implicitly by destroy and repair method. A destroy method destructs part of the current solution while a repair method rebuilds the destroyed solution. The destroy method typically contains an element of stochasticity such that different parts of the solution are destroyed in every invocation of the method. The neighbourhood $N(x)$ of a solution x is then defined as the set of solutions that can be reached by first applying the destroy method and then the repair method. Here there are N identical vehicles of capacity C and M customers.

4.1 Location

The first step in the VRP Spreadsheet Excel solver is to secure a Bing Maps key to use the Macro that has been enabled in Excel. The first excel sheet seeks details of company and bus stops along with the number of passengers boarding/unboarding, option of pickup and delivery, average estimated vehicle speed, location of nodes, time windows etc. All information is compiled in the first excel worksheet shown in Table I.

TABLE 1: Location population sheet (Captures Latitudes and Longitudes of Company & Bus Stops)

4.2 Setup Distances Sheet

The distance of the company and bus stops is calculated from the first excel sheet and a second distances sheet is populated by the solver. Furthermore, the duration from the depot to the destined location is also calculated. To improve the accuracy in the duration calculation, it is recommended that time input is given with a specific window in the start of the use of this macro.

The blank distance sheet looks like the one shown in table II and a populated distance sheet specifying the distances between various nodes (company and bus stops) is generated by solver as shown in table III.

TABLE 2: Distances worksheet generated by solver

	A	B	C	D

Depot	Customer 21	0.00	0:00

4.3 Setup Vehicles Sheet

The third sheet generated seeks information related to vehicles such as vehicle type, name, capacity, fixed cost per trip, cost per unit distance, available number of vehicles as shown in tables IV & V.

TABLE 4: Vehicle Parameters sheet as generated by the solver

A	B	C	D	E	F
Vehicle type ID	Type name	Capacity	Fixed cost per trip	Cost per unit distance	Number available
1	A	1	0	1	1

TABLE 5: Vehicle Parameters sheet as modified to suit case study parameters

A	B	C	D	E	F
Vehicle type ID	Type name	Capacity	Fixed cost per trip	Cost per unit distance	Number available
1	A	30	0	1	4

4.4 Solutions, Solver and Visualization

On successful entry of all information in the first three excel sheets, the solver validates it and generates solutions worksheets as shown in tables VI & VII. The said solution is generated on bing maps automatically showing the pictorial path of each individual vehicle route as shown in figure 1.

As shown in tables VI & VII, the solutions worksheet specifies all vehicles and route both on the excel solutions sheet as well as bing maps. It includes the vehicles used, number of nodes (bus stops) served, the optimized route formed indicating the sequence of nodes, distance travelled between all consecutive nodes on each route, vehicle arrival and departure time at each node, waiting times, if any. This takes into consideration a majority of practical aspects making this approach valid and useful in solving real life vehicle routing problems. To increase the specificity and the accuracy, it is essential to input parameters that are closest to the actual scenario.

Fig. 1. Bing Maps solution showing the routes obtained for case study

5. CONCLUSION

Solving a vehicle routing problem effectively is not easy, let alone the usage of softwares to solve it. It can be seen that some softwares do exist that provide alternative algorithms that solve such VRPs. Most simplest and workable of all is the VRP Spreadsheet Solver macro, an effective tool to use for companies that are small scale and upwards. It is open-source and hence is free to use upon downloading. Constraints can be input as per the need into the solver and it will give a solution (upto 200 entities). However, it does not account for real time traffic data, and hence you may arrive at a route whose feasibility should be checked with a map. That being said, the solution that the

VRP Spreadsheet Solver macro for Excel provides is essentially much easier to obtain than a normal vehicle routing problem that may have plenty of variables.

SECTION – IV
PLANT LAYOUT AND LOCATION

Flexible Bay Dynamic Facility Layout Problems using Aisle Structure

S. Ingole, D. Singh

Department of Mechanical Engineering
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

Abstract: Dynamic facility layout problem (FLP) is the task of locating the positions of the facilities/departments on available floor space for certain planning horizons that provide minimum material handling cost. The design of facility layout is incomplete without consideration of aisle structure for material handling and personnel travelling. This paper presents a method to solve dynamic FLP with flexible bay structure (FBS) having aisles or passages. In FBS, the facilities are arranged in horizontal or vertical bays of varying width. In first stage, the dynamic FLP with FBS are solved using biogeography-based optimization (BBO) algorithm and in second stage an aisle structure is developed for material and personnel flow.

Keywords: Dynamic facility layout problem, flexible bay structure, aisle construction, biogeography-based optimization

1. INTRODUCTION

In present manufacturing environment, the product demands are volatile in nature. Therefore the facility layout should be flexible to changing demands which is called as dynamic facility layout. In dynamic layout, the arrangement of facilities/departments for one planning period should be easily reconfigurable for next planning period with minimum cost. In this paper, we are considering dynamic, unequal-area FLPs with flexible bay structure. In most of the real industries the facilities are unequal in shape; therefore in this paper main focus is given on the unequal area FLPs. Dynamic FLPs are addressed by many of the researchers; however their study is limited to equal area dynamic FLPs while very few researchers studied unequal area dynamic FLPs. In previous literature, very few researchers considered aisles while solving a FLP. However, while designing any layout, aisles or passages are integral part of the layout for smooth and suitable flow of material and workers. Therefore in this paper, a new structure of aisles is developed for unequal area facility layout with flexible bay structure (FBS). Till date, dynamic FLPs having FBS are attempted by a researcher with only 12 departments which is considered as small size FLP. Therefore, a pseudo problem is generated randomly having 20 departments with two planning periods. In first stage, the dynamic FLP of 20 departments is solved using one of the most efficient metaheuristic method i.e. BBO algorithm to obtain best solution and in second stage, a potential aisle structure is explained for proper material flow.

2. LITERATURE REVIEW

The extensive literature reviews were carried out for dynamic FLPs and FLPs considering aisles. The literature review is categorised as below:

2.1 Dynamic FLP

The first study on dynamic facility/plant layout is done by Rosenblatt (1986). The multi-period FLP is modelled using dynamic programming and solved using a heuristic method. Balakrishnan et al. (2000) proposed two algorithms, namely dynamic programming and pair-wise exchange heuristic to solve dynamic FLP to minimize material handling cost and rearrangement cost of facilities during different planning periods. Balakrishnan et al. (2003) implemented hybrid genetic algorithm (HGA) to optimize 6, 15 and 30 department DFLP and compared with other algorithms. Dunker et al., (2005) presented an algorithm combining dynamic programming and genetic search for solving a DFLP with unequal areas. McKendall and Shang (2006) proposed hybrid ant systems to solve DFLP with 5 and 10 periods of planning horizon. Sahin and Turkbey (2009) presented a new hybrid heuristic based on the simulated annealing (SA) approach supplemented with a tabu list for the DFLP.

Emami and Nookabadi (2013) attempted DFLP with multi-objective function having equal area facilities and optimized using non-dominated sorting GA and Pareto-simulated annealing algorithm. Chen and Lo (2014) presented DFLP with multi-objective function and optimized using ACO. The industries such as footwear and clothing are prone to seasonal demand changes, thus, time horizons and layout/re-layout of the machines within the facility should be studied carefully (Ulutas and Islier, 2015). They considered a footwear facility layout and several scenarios are generated by using the real life data. A clonal selection based algorithm is proposed to solve the real life DFLP. Remanufacturing is a preparation of rising importance due to increasing environmental awareness and regulations (Li, et al. 2015). They presented an optimization

method for remanufacturing dynamic facility layout with variable process capacities, unequal processing cells, and inter-cell material handling.

2.2 FLP with aisles

Wu and Appleton (2002) presented a combined method to optimize the facility layout and aisle structure by SA. Slicing structure is used for layout design and the slicing lines on the floor are used as the aisle structure for the material handling. Gomez et al. (2003) applied GA to solve factory layout problems by considering passageways. Lee et al. (2005) explained the formulation for multi-floor, unequal area FLP with inner structure walls and passages and solved using improved GA. Ye and Zhou (2007) developed a new local GA hybridized tabu search, to solve multi-criteria FLPs by considering fixed aisles and transverse passageways between sections. Alagoz et al. (2008) introduced a method for finding useful aisle structures for a given flexible bay block layout.

3. MATHEMATICAL FORMULATION OF DYNAMIC FLP

The dynamic FLP having unequal area can be formulated as follows (McKendall and Hakobyan, 2010):

$$\text{Minimize } F = \sum_{t=1}^T \sum_{i=1}^N \sum_{j=1}^N f_{tij} d_{ij} c_{ij} + \sum_{t=2}^T \sum_{i=1}^N \sum_{j=1}^N A_{tij} Y_{tij} \quad (1)$$

$$MHC(s) = \sum_{i=1}^n \sum_{j=1}^n f_{ij} d_{ij} c_{ij} \quad (2)$$

$$\alpha_i = \frac{\max\{l_i, w_i\}}{\min\{l_i, w_i\}} \leq \alpha_{max} \quad (3)$$

$$l_i^{min} = \min\{l_i, w_i\} \quad (4)$$

$$P_c(s) = (n_s)^k \times MHC(s) \quad (5)$$

Where

F - Total material handling and rearrangement cost

N - Number of departments or the locations

T - Number of periods

f_{tij} - Material flow in period t between department i to department j

d_{ij} - Rectilinear distance between the centroids of locations j and i

c_{ij} - Unit cost between department i and j

A_{tij} - Fixed cost of moving department i to j at period t

Y_{tij} - 0, 1 variable for shifting facility i to j in period t

$MHC(s)$ - Material handling cost of layout s in period t ,

α_i - Aspect ratio of facility i ,

α_{max} - Maximum allowable aspect ratio,

l_i^{min} - Minimum side length of facility i ,

$P_c(s)$ - Penalty function for infeasible facilities in layout s ,

n_s - Number of infeasible facilities in layout s ,

k - Severity parameter of the penalty function

The value of k is decided by layout problem solver (Ulutas and Kulturel-Konak, 2012). If the minimum side length of facility is less than l_{min} then the facility is infeasible.

3.1 Construction of aisle structure

Assuming that the optimal layout is obtained which is shown in Fig. 1 (a). The facilities are arranged in flexible vertical bays, starting from top left corner in downward direction. The shaded space on the right side of the layout will be accommodated by the aisles. The facilities will shift to right side, when the aisles are designed.

(a)

(b)

Fig. 1(a) 20-department layout (b) Layout with aisles

In the layout, it is assumed that four aisles shown as coloured in Fig. 1(b) are necessary which are defined as follows (Alagoz et al., 2008):

- 1) The right-hand side of the first bay
- 2) The left-hand side of the last bay
- 3) Top horizontal line between first and last bay4)
Bottom horizontal line between first and last bay

These four aisles are considered because they are convenient, long and vertical which are suitable for material handling equipment and travelling of persons.

Furthermore, we need possible aisles to travel from second and second last bay. Both the right-hand and left-hand side of the bays between the first and last bays are considered as fixed aisles as shown in Fig. 1(b). Further, for convenience of material handling, short horizontal aisles between the facilities are considered. From Fig. 1(b), it is clear that, the upper boundary of facilities 10, 14 and 19 is almost near to each other as compared to other facilities. Therefore, these three aisles are considered as horizontal aisles in the layout. Finally, the total number of aisles in the layout is nine; four vertical and five horizontal. The width of the aisle is fixed and it is decided according to the size of material handling equipment. The area of the layout should be large enough to accommodate the aisles.

4. BIOGEOGRAPHY BASED OPTIMIZATION ALGORITHM (BBO)

BBO algorithm comes under the category of population-based evolutionary algorithms and it is developed by Simon in 2008. BBO is based on concept of island biogeography in which topographical distribution of living species is explained (Alroomi et al., 2013). The working procedure of

BBO is developed by considering the migration of species from one island to another. On an island or habitat, if the conditions of living are well suited for species then that habitat have high suitability index (HSI), because this habitat have better features than other habitats. The habitability is illustrated as suitability index variables (SIVs). Habitats with high HSI have more number of species as compared to low HSI habitats. Therefore, the species on the high HSI habitats can emigrate to other habitat and have low species immigration rate as the population of species is high. Similarly, the low HSI habitats have high species immigration rate as there is very low population.

5. APPLICATION OF BBO ALGORITHM TO 20-DEPARTMENT DYNAMIC FLP

The 20 department FLP is generated for two periods of planning horizon. The specifications are given below:

Number of departments = 20; Length of layout (L) = 18; Width of layout (W) = 24;

Area of total layout = $L*W = 18*24 = 432$; Aspect ratio (α_{max}) = 5; Number of time periods (T) = 2;

Rearrangement or shifting cost (R_{it}) = 10 (for all departments);

Areas of the departments = {19, 16, 29, 19, 13, 29, 30, 19, 12, 15, 18, 22, 15, 22, 24, 14, 12, 16, 16, 18}

5.1 Results of 20 department FLP using BBO

The material flow data for first and second period is shown in Table 1 and 2 respectively. The results are shown in Table 3.

9	119055	92.13
10	120663	89.03
Average	117630	91.19

Table 3 shows the total layout cost for both the planning periods using BBO. The algorithm runs for 10 trials to see the performance of BBO on dynamic FLP. It is observed that in every trial, the value of total layout cost obtained is not much different than the best value. The computational time required for one trial of BBO algorithm is shown in seconds. The average of total layout cost and time is calculated to show the deviation from the best values. The best layouts for first and second planning period are shown in Fig. 2.

Fig. 2. Best layouts of 20-department dynamic FLP

5.2 Aisle construction for 20-department dynamic FLP

The possible aisle structures for first and second planning periods are shown in Fig. 4. In Fig. 3, it is seen that the space in right side is blank. This space will be utilised to design the aisles. As discussed in section 3.2, the aisles are constructed on the boundaries of bays. After allotting space for aisles, the areas of the departments will be reduced this will cause infeasible departments. As shown in Fig. 4, after construction of first aisle on the right boundary of first bay, the departments on the right side of first bay will be shifted to right side by the amount of length equal to the width of the first aisle. In this manner, all the aisles are constructed. The aisle width is decided according to the width of the material handling equipment.

In Fig. 4, it is seen that there are total seven aisles, four vertical and five horizontal. The upper boundaries of departments 16, 14 and 2 are nearly on same height; hence these two aisles are possible aisles. After positioning these aisles, the total layout area is utilised. In Fig. 4, departments 19, 16, 10, 18, 14, 17, 5, 1, 2, 3, and 4 will reduce in area, because aisle structure consists of these departments only. The utilisation of blank space in the layout is described below:

Number of vertical aisles = 4; Number of horizontal aisles = 3

Number of vertical bays or rows = 5; Widths of the bays = {3.28, 2.5, 2.11, 6.0, 7.11}

String of the departments = 6-7-19-16-10-18-14-17-5-1-2-3-4-11-15-20-9-8-12-13

Lengths of the departments = $\{l_6, l_7, l_{19}, l_{16}, l_{10}, l_{18}, l_{14}, l_{17}, l_5, l_1, l_2, l_3, l_4, l_{11}, l_{15}, l_{20}, l_9, l_8, l_{12}, l_{13}\}$
 $= \{8.85, 9.15, 6.4, 5.6, 6.0, 7.58, 10.42, 2.0, 2.17, 3.17, 2.67, 4.83, 3.17, 2.53, 3.37, 2.53, 1.68, 2.67, 3.09, 2.11\}$

Widths of the departments = $\{w_6, w_7, w_{19}, w_{16}, w_{10}, w_{18}, w_{14}, w_{17}, w_5, w_1, w_2, w_3, w_4, w_{11}, w_{15}, w_{20}, w_9, w_8, w_{12}, w_{13}\}$
 $= \{3.28, 3.28, 2.5, 2.5, 2.5, 2.11, 2.11, 6.0, 6.0, 6.0, 6.0, 6.0, 6.0, 7.11, 7.11, 7.11, 7.11, 7.11, 7.11, 7.11\}$

Total area of layout = 432; Total area of all the departments = 377.83

Blank area = (Total area of layout - Total area of all the departments) = 54.17

Length of blank area = 18; Width of blank area = 3; Width of aisle = 0.2

Total width of vertical aisles = $4 \times 0.2 = 0.8$

Width of blank area after placing aisles

$= (\text{Width of blank area} - \text{Total width of vertical aisles}) = (3 - 0.8) = 2.2$

From above discussion, it is clear that the widths of the bays and departments are adjusted satisfactorily by shifting to right side. Now, the lengths of the departments will also reduce due to horizontal aisles.

Total width of horizontal aisles in 2nd bay = $3 \times 0.2 = 0.6$

Total width of horizontal aisles in 3rd bay = $3 \times 0.2 = 0.6$

Total width of horizontal aisles in 4th bay = $3 \times 0.2 = 0.6$

As, there are three departments in 2nd bay, hence the lengths of the departments 19, 16 and 10 will reduce by 0.2 units each. The length reduction will be uniform throughout the bay. In 3rd bay, the lengths of departments 18 and 14 will be reduced by 0.3 units each. In 4th bay, there 6 departments, therefore the length of departments 17, 5, 1, 2, 3 and 4 will be reduced by 0.1 unit each. New lengths of departments will be calculated by subtracting the reduction from original length (new $l = l - \text{reduction}$) as follows:

{6.2, 5.4, 5.8, 7.28, 10.12, 1.9, 2.07, 3.07, 2.57, 4.73, 3.07}

After calculating the reduced lengths of the departments, the feasibility of the departments are to be checked using the constraint of maximum allowable aspect ratio of the departments which is $\alpha_{max} = 5$. Aspect ratio can be calculated by dividing the larger side of the department to shorter side. New calculated aspect ratios are as follows:

{2.48, 2.16, 2.32, 3.45, 4.79, 3.15, 2.89, 1.95, 2.33, 1.27, 1.95}

The aspect ratios of all the above departments are within the limit. So, these departments are feasible. The area reduction of the department due to reduced lengths is:

Total area reduction of the departments = 3.6

*Total area of vertical aisles = no. of vertical aisles * (width of aisles*length of aisles)*

*= 4 * (0.2 * 18) = 14.4*

Total area required by aisles = (Total area reduction of the departments+ Total area of vertical aisles)

= 3.6 + 14.4=18

The area of blank space is 54.17, which is more than the total area required by aisles. Therefore, the design structure of aisles can be successfully implemented on unequal area FLP with FBS.

Fig. 3 shows the aisle structure for second period, respectively. In second planning period, there are five horizontal aisles and four vertical aisles.

Fig. 3. Best layouts with aisles

As the number of aisles increases, the aisle construction cost and total layout cost will also increase. In this paper, the aisle construction cost is not considered, but from above construction design the layout planner can get idea of the cost of aisle construction, which will be beneficial for layout design.

6. CONCLUSION

Today's manufacturing industry is changing very fast; it means that the layouts are not static for longer period of time. The market is dynamic in nature, therefore while designing the layout, several time periods should be considered and the rearrangement cost is calculated. In many research articles, aisles or passages are not considered for material flow. This can lead to poor layout solutions. To avoid this drawback, an aisle construction procedure is described. The presented aisle structure is implemented on a randomly generated dynamic FLP of 20 departments with two planning horizons. The problem is solved using flexible bay structure and optimized using BBO. After obtaining the optimal layouts for all planning periods, the possible aisle structure is described which is easy to understand and flexible to design for convenient material flow.

Facility Layout Problem Using Firefly and Biogeography-Based Optimization Algorithms

S. Ingole, D. Singh

Department of Mechanical Engineering
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

Abstract: *Appropriate floor space optimization is referred as facility layout problem (FLP). Various FLPs are studied by researchers in all the fields of engineering. Theoretical work published by previous researchers on FLP has less relevance to real life problems of facility layouts. Therefore, an industrial case-study is carried out in plastic manufacturing company and presented in this paper. The FLP of the industrial case-study is formulated to minimize total material handling cost. Two metaheuristic techniques namely firefly algorithm (FA) and biogeography-based optimization (BBO) algorithm are applied to obtain the optimized solutions for the FLP of the considered case-study. Both the algorithms are providing better results than the original layout cost, however the solution quality of BBO is better than FA.*

Keywords: *Facility layout problem, unequal area facilities, firefly algorithm, biogeography-based optimization*

1. INTRODUCTION

The major goal of a manufacturing industry is facility layout design which is a necessary foundation and can be called as facility layout problem (FLP). An appropriated planning of facility layout includes many aspects such as material to be handled, machines, material handling equipment, ventilation, passageways employees/workers to construct the efficient layout. Facility layouts are classified as equal area facility layout, unequal area facility layout, single row facility layout, multi-floor facility layout. In actual practise, the layout planner is encountered with unequal area FLP, therefore the same is considered in this paper for a real case-study in an industry. The FLP formulation is quadratic assignment programming (QAP) with the objective of minimization of total material handling cost.

In previous literature, less attention is given on real case-studies of manufacturing industries and hence it is difficult to connect the solutions obtained for benchmark problems in previous literature to the FLP of an industry. Therefore, in this paper it is attempted to solve FLP of plastic manufacturing company and the total material handling cost or layout cost is optimized using two efficient non-traditional optimization techniques i.e., firefly algorithm (FA) and biogeography-based optimization (BBO) algorithm. The results obtained using FA and BBO are better than the original layout cost; however BBO algorithm is outperforming FA in terms of solution quality.

2. LITERATURE REVIEW

The literature review focuses on the unequal area FLPs and the considered metaheuristic techniques FA and BBO. In 1992, Tam described unequal area FLP with slicing tree

structure with the constraints of aspect ratio and dead space ratio and he applied simulated annealing (SA) algorithm to obtain results. Kim and Kim (1995) proposed a graph theoretic heuristic, in which the initial layout was generated and get improved through a local search technique. Schnecke and Vornberger (1997) implemented hybrid genetic algorithm (HGA) to solve unequal area FLPs with tree structure. Later, Lee and Lee (2002) introduced a shape-based block layout (SBL) approach for solving fixed-shape unequal area FLPs using HGA. Scholz et al. (2009) approached both fixed and flexible shape FLPs using tabu search (TS) technique.

FA is well-known technique to solve various optimisation problems. An application of FA for single row FLP is described by Sonmez and Baray (2013). Sayadi et al. (2010) presented discrete FA to solve permutation flow shop scheduling problems. Jati and Suyanto (2011) implemented FA to TSP.

Sayadi et al. (2013) applied FA to solve manufacturing cell formation problems. Ingole and Singh (2016) implemented FA to solve unequal area, fixed shape FLPs. It is observed that FA has wide domain of applications including combinatorial optimization problems. BBO is one of the most applicable techniques to obtain optimized solutions of problems. Rahmati and Zandieh (2012) developed the BBO algorithm for flexible job shop scheduling problem (FJSP). An application of BBO is described by Sooncharoen et al. (2015) for the machine layout design problems to minimize the material handling distance. Lim et al. (2016) proposed a hybrid technique combining BBO and TS to solve QAP and obtained better results within reasonable computational time.

3. MATHEMATICAL FORMULATION OF UNEQUAL AREA FLP

FLP having unequal shapes and size of facilities can be arranged as fixed shape or flexible shape. These FLPs are approached by some researchers; Schnecke and Vornberger (1997) and Scholz et al. (2009) used slicing tree structure and Lee and Lee (2002) used flexible bay structure. In this FLP, number (n) of facilities/departments of width w and length l are assigned on the floor layout space having total length (L) and width (W). The objective function for the FLP of industrial case-study is as follows:

$$\text{Minimize } F = \sum_{i=1}^n \sum_{j=1}^n f_{ij} d_{ij} c_{ij} \quad (1)$$

Subject to

$$d_{ij} = |x_i - x_j| + |y_i - y_j| \quad (2)$$

$$\sum_{u=1}^k l_u \leq 1.25 \sqrt{\sum_{v=1}^n A_v} \quad (3)$$

$$O_{ij} = \beta_{ij} (\lambda_{xij}) (\lambda_{yij}) \quad (4)$$

$$\lambda_{xij} = \left(\frac{l_i + l_j}{2} \right) - |x_i - x_j| \quad (5)$$

$$\lambda_{yij} = \left(\frac{w_i + w_j}{2} \right) - |y_i - y_j| \quad (6)$$

$$\beta_{ij} = \begin{cases} 0 & \text{for } \lambda_{xij} \leq 0 \text{ and } \lambda_{yij} \leq 0 \\ 1 & \text{otherwise} \end{cases}$$

F -Objective function to minimise the material handling cost (MHC)

i, j = facility index (1, 2, ..., n)

n = number of facilities/departments

c_{ij} = cost of one unit of material flow between facilities i and j

f_{ij} = amount of material flow between facilities i and j

d_{ij} = rectilinear distance between locations of facilities i and j

l_u = length of facility

A_v = area of facility

$u = 1, 2, \dots, k$ (facility index for number of departments in a bay)

$v = 1, 2, \dots, n$

O_{ij} Overlapping constraint

l_i and l_j are lengths of departments i and j

w_i and w_j are lengths of departments i and j

4. FIREFLY ALGORITHM (FA)

FA is a new optimization technique developed by Yang in 2010. It is inspired by the behaviour of attraction among the fireflies and deals with their variations of light intensity (Yang, 2010). The algorithm steps of FA are as follows:

Step 1: Randomly generate initial population of fireflies. Set the parameters such as number of fireflies, generations, absorption coefficient (γ), randomization parameter (α)

Step 2: Define objective function and evaluate intensity of light (i.e., fitness value) for all fireflies.

Step 3: According to the intensity value, select the best firefly.

Step 4: Calculate the distance of best firefly from other fireflies and update the positions of fireflies.

Step 5: Evaluate firefly intensities and rank the firefly intensities.

Step 6: Select the best firefly for the iterations.

Step 7: Update the fitness values and if the iterations reach the maximum generation limit, then stop else go to step 4.

5. BIOGEOGRAPHY-BASED OPTIMIZATION (BBO)

BBO algorithm is developed by Simon in 2008 which is a population-based evolutionary algorithm. BBO algorithm shares information from one island to other through migration and mutation. BBO algorithm is based on theory of island biogeography in which geographical distribution of biological species is explained (Alroomi et al., 2013). BBO algorithm follows migration and mutation operations to reach global minimum solution. The variables that describe habitability of an island are called as suitability index variables (SIVs) (Simon, 2008). Each island is considered as one solution. By considering the emigration (μ) and immigration (λ) rates of each member, the information between the habitats is shared probabilistically. BBO steps are as follows:

Step 1: Initialise BBO parameters i.e. number of islands or number of layouts (S), each island represents the permutation of facilities from $n = 1, 2, \dots, k$, generations of algorithm (G), maximum immigration rate (I), maximum emigration rate (E), maximum number of species on an island (S_{max})

Step 2: Evaluate the fitness function or objective function

Step 3: Calculate the values of μ and λ . Sort the values in descending order to map them according to emigration and immigration.

Step 4: Apply migration operator to modify the SIVs. The good features and information is shared between habitats or islands. This depends on emigration rates μ and immigration rates λ of each solution.

Step 5: Mutation is done to increase the diversity of the population members to obtain the good solutions.

Step 6: Clear any duplicated islands and evaluate the fitness function.

Step 7: Find the best minimum value. If the stopping criteria satisfied terminated the algorithm else go to step 4.

6. APPLICATION OF FA AND BBO ON FLP OF CASE-STUDY

This case-study is performed at Nagpur shrink pack limited, MIDC, Nagpur, Maharashtra. The products manufactured in this facility layout are poly vinyl chloride (PVC) blown

films, printed plastic labels, plastic pouches, food packaging plastic bags, etc. The total length (L) of the layout is 28.48 metres and the width (W) is 11.54 metres. The machines and their dimensions are given in Table 1. The material flow matrix is shown in Table 2.

TABLE 1: Dataset of case-study

Sr. No.	Departments	Length	Width	Area
1	Raw material storage	7.72	4.44	34.28
2	Mixing and compounding	7.72	3.40	26.25
3	Office	3.35	3.22	10.78
4	Extruder 1	7.96	3.22	25.63
5	Extruder 2	6.46	1.76	11.37
6	Slitting machine	2.71	3.20	8.67
7	Film cutting machine	2.50	2.74	6.85
8	Core cutting machine	1.60	3.70	5.92
9	Compressor room	1.40	3.70	5.18

TABLE 2: Material flow (Tons/month)

f_{ij}	1	2	3	4	5	6	7	8	9
1	0	27	-	-	-	-	-	-	-
2	-	0	-	22	5	-	-	-	-
3	-	-	0	-	-	-	-	-	-
4	-	-	-	0	-	15	-	-	-
5	-	-	-	-	0	2	-	-	-
6	-	-	-	-	-	0	10	3	-
7	-	-	-	-	-	-	0	-	-
8	-	-	-	-	-	-	-	0	-
9	-	-	-	-	-	-	-	-	0

In this problem, the layout shape is not rectangular. Some portion of the layout is unused. This unused space is shown in the current layout of case-study 4 as shown in fig. 6.7.

The grey shaded portion is used for material flow using hand trolleys. The original layout cost is 170.58.

Fig. 1. Original layout of case-study (Nagpur shrink pack limited)

6.1 Results of case-study using FA and BBO

Case-study 4 is solved using the mathematical formulation

of unequal area FLP with fixed shape of facilities. The parameter setting of FA and BBO are shown in Tables 3. Both algorithm runs for 10 trials.

TABLE 3: Parameter setting of FA and BBO

Sr. No.	FA		BBO	
	Parameters	Value	Parameters	Value
1.	Number of fireflies (nff)	50	Number of islands	50
2.	Generations	100	Generations	100
3.	Absorption coefficient (γ)	2	Emigration (E)	1
4.	Randomization parameter (α)	0.3	Immigration (I)	1
5.	The attractiveness (β_0)	1	Mutation rate	0.2

TABLE 4: Results of case-study using FA and BBO

Sr. No.	FA		BBO	
	OFV	CPU time (s)	OFV	CPU time (s)
1	180.24	35	201.89	30
2	225.69	39	189.23	33
3	238.10	41	175.45	28
4	191.25	33	153.20	26
5	210.08	38	179.23	36
6	198.25	45	205.90	28
7	173.54	35	188.45	27
8	179.91	39	195.68	32
9	186.47	36	200.56	34
10	195.00	31	193.26	34
Average	197.85	37.2	188.25	30.8

Table 4 shows the results obtained using FA and BBO for case- study 4. The best solution is 153.20 and obtained using BBO. The computational time (CPU time) for FA and BBO to run each trial and its average is shown in Table 6.16. FA is also providing better results than the original solution but not better than BBO.

Fig. 2. Best layout obtained using BBO algorithm

The best layout obtained using BBO is shown in Fig. 2. It can be seen that the facility no. 3 is apart from the facilities carrying treatment of toxic material. Furthermore, the total layout cost is minimized as compared to original layout. From this case-study, it can be concluded that there will be requirement of optimized layout arrangement in the existing layout; which can optimize the total material handling cost resulting in long-time benefit to the industry. In this paper, FA and BBO algorithms are implemented to solve the case-study and it is giving better solutions than the existing solutions. The performance of BBO algorithm is better than FA. The CPU time to run BBO algorithm is less than FA. Therefore, BBO algorithm is efficient to solve FLPs.

7. CONCLUSION

An optimum layout is very important in practical point of view. The solutions of benchmark problems are little relevant to real life problems. Therefore, in this paper an industrial case-study is carried out to observe the real FLP. The FLP considered of plastic manufacturing industry consists of nine departments. FA and BBO metaheuristic techniques are used to obtain the best optimum results of the unequal area FLP of industrial case-study. The solutions obtained using both the algorithms are better than the total material handling cost of the original layout; however the performance of BBO algorithm is better than FA in terms of solution quality and the computational time. If the existing layout is modified according to the layout obtained in this paper, then the overall layout cost will be reduced which will be beneficial for the industry.

A Literature Review on Facility Planning and Layout Design

Vinay Y Pawar, Ajay S Bonde

Department of Mechanical Engineering
Yeswantrao Chavan College of Engineering, Nagpur, Maharashtra, India

Abstract: Planning and pre work during a relocation of a plant in an Industry is very vast area to work on. Planning and pre work includes facilities planning, layout planning and systematic installation of equipment's and machines that are essential in a manufacturing industry. During working on facilities planning it is also important to work on the new proper streamline layout for the new plant. This proper streamline layout will not only increase the production but also minimize the material handling of the components. The purpose of this paper is to study and review the contribution of various researchers in the field of relocation and facilities planning.

Keywords: Layout, facilities planning, virtual layout planning, relocation.

1. INTRODUCTION

Proper installation of equipment's in the specified area in the plant is called facility layout problem. Facility layout problem plays an important role in the present and the future scenarios, it will have severe impact on major and long term material handling, lead time of product and work in progress as well as the efficiency will be affected. The proper installation of the machineries and the equipment's can definitely increase the productivity of the organization. Many researchers have worked on the type of facilities planning as well as facilities planning for the relocation of the facilities. It is very important to review the research papers to see if any research gap exists. It is also important to study research papers if any improvements can be done in this field.

The reason for relocation of an organization depends on various aspects like end of lease at current location, to make space for the new product, to bring the facility nearer to the customers, etc. While designing a new layout it is also essential to work on the optimization of the layout design. There are tools that can be used to optimize a layout design like heuristic method, simulation technique, etc. There are also lots of techniques that are used to assist for the problems that occur during designing a facility layout. These techniques are CRAFT, ALDEP, CORELAP, M-CRAFT, BLOCK PLAN, MULTIPLE, etc. Proper care must be taken that the efficiency of that organization should not be reduced while planning for new layout. Every organization needs that their productivity must be increased when they want to relocate or plan for new layout design.

2. TOOLS FOR OPTIMIZING LAYOUT DESIGN: HEURISTIC METHOD

These heuristic methods used for optimizing layout design are experimental or theoretical methods. There are many

heuristic methods that can be used to optimize the layout namely Simulated Annealing, Tabu Search, Genetic Algorithms. Tabu search is heuristic method first introduced in 1986 by Fred Glover. Tabu search is the extension of the local search technique which was used before the application of the tabu search technique. Fred Glover thought of tabu search as a Meta heuristic technique used for mathematical optimization.

Genetic algorithm is to solve the optimization problems; it was invented by John Holland in the 1970's. Genetic algorithm gives best optimizing solution from the results.

3. TOOLS FOR OPTIMIZING LAYOUT DESIGN: SIMULATION TECHNIQUE

Simulation technique is an artificial way to show the real processes or some real things. Simulation techniques shows the most realistic scenarios of the required area or space in the layout just like virtual reality or augmented reality. A simulation model is created as an analyzing technique to look for fluctuations in the future demands. Simulation techniques are used to assist management decision making where improper analytical methods are available.

4. REASONS FOR DESIGNING NEW LAYOUT

- Increase in the bottlenecks at the existing layout.
- For making the introduction of new machines in the organization.
- If the organization wants to change the design of the products or services.
- Relocating the plant
- The space available is less at the existing layout.
- Running out of lease.
- Improper material handling facility.

5. LITERATURE REVIEW

Ayşe Durukan Sonmez and Gino J. Lim (2012) discussed the two challenges occurring during the facility relocation related to the future demand change and uncertain number of the future facilities. A mathematical model was introduced to reduce the distance traveled by the customers in present as well as in the future. The performance of the mathematical model was compared to the various methods that were obtained in the literature surveys and also sensitivity analysis was performed. The objective was to minimize the sum of current weighted distance travelled by the customers to their closest facilities without exceeding the budget required for closing and opening of facilities.

Ali Taghavi and Alper Murat (2011) presented an iterative heuristic procedure for solving the problems related to the layout design and product flow assignment. Proposed a heuristic methodology to solve small to large problems with the best solution. An experimental study was conducted to compare the proposed solution method to the exact solution method. The results obtained were both effective and efficient solutions for any occurring problems. Further these tests can also be conducted on stochastic and dynamic extensions of integrated layout design.

M. H. Kulkarni, S. G. Bhatwadekar and H.M. Thakur (2015) presented a broad literature review on facility layouts and plant layouts. The brief study of literatures is done in area of facility layout problem, types and methodologies to solve the facility location problem. Authors also stated the need for the re-layout, layout configurations and inputs that will be required to design a proper layout. Also various aspects that are required while designing the layout such as area of the location, number of machines, numbers of products, etc. are discussed in this paper.

Sanjeev Naik and Dr. Shrikant Kallurkar (2016) published a review paper based on plant layout as well as re-layout. The tools that are required for optimizing the layout design are also mentioned in this paper. Talked about the heuristic techniques like Tabu search (TS), Simulated annealing (SA) and Genetic Algorithm (GA). Discussion was done on those research papers and the shortcomings were also found out in those papers. This paper is mainly focused on the optimization of the layout design and the tools required for optimization.

S. Jiang and A. Y. C Nee (2013) worked on the novel factory planning system for on-site facility layout planning (FLP). Two FLP modules are used by the author manual and automatic. An Augmented Reality (AR) layout was used for facility layout planning for the existing layout. An Augmented Reality (AR) based model of the layout is the computer generated image that shows the real world view of the layout. An Augmented Reality is used for visualization of the layout process like Proper installation of

the equipment's can be shown on the Augmented Reality (AR) system which can show if the equipment can be placed in that area. It was also stated that an Augmented Reality (AR) based facility layout planning (FLP) has some drawbacks like it can become ineffective for large scaled and complex layouts and manual planning can be challenging and difficult.

Eida Nadirah Roslin and Ong Gee Seang (2008) developed a design of a facility layout for the production line in the organization. WITNESS simulation software used for the facility layout design. A case study was conducted by the authors in a lubricant manufacturing company to work on its production line in the manufacturing department. WITNESS software uses various data such as process flow, machine cycle time, product cycle time, material handling, part delivery schedule, etc. to simulate and give the output. Using WITNESS simulation software two layout designs will be created based on the data provided. Analysis is done of those models of layout and the best model is selected between those two. By the simulation software two flow patterns are created namely S shape flow pattern and U shape flow pattern. After the studies were done U shaped design was found to be more effective compared to the S shaped design. Authors also stated that for future material handling, safety and proper arrangement of the machines and proper method of working to be done.

Hari Prasad N., Rajyalakshmi G. and Sreenivasulu Reddy A. (2014) created a layout design using a computerized relative allocation of facilities technique (CRAFT). The objective is to create an optimized layout by giving input of STEP file into the software. CRAFT was proposed by Buffa et al, and is also called as computerized heuristic algorithm. To develop a JAVA program inputs are required to be entered such as number of departments, initial layout of the organization taken from AutoCAD, cost matrix and flow matrix. The AutoCAD file of the initial layout should be converted into a STEP file format. It was seen that by using the CRAFT more than 50% of the cost was reduced of optimizing layout compared to the initial layout.

Srinivasan Rajagopalan and Sunderesh S Heragu (1997) did their research in the area of facility layout and material handling. To increase the productivity it is very important to provide a proper material handling systems and space while designing a facility layout. Many design related problems are faced due to less material handling space available which will discourage the workers and also the productivity becomes less, hence the authors discussed a methodology to solve these types of design related problems and any other problems. This paper also outlined an idea to solve the problems occurring in the material handling flowpath as well as pick up and drop off point location. They also talked about making a proper layout with a flowpath for movement of automated guided vehicles (AGV). AGV provides less material handling by

the humans which would result in less accidents and improper material handling. The authors also talked about quadratic assignment problem (QAP) which is one of the methods to solve problems occurring while layout designing.

S. Jiang, S. K. Ong and A. Y. C. Nee (2014) presented an augmented reality (AR) based hybrid approach for on-site planning of layout and evaluating it in real time. A system named an AR based hybrid approach to facility layout planning and evaluation (AHFLE) is used for automatic planning and manual planning. In AHFLE, parallel tracking and mapping (PTAM) is used for real time tracking of the activities done by the planner. Using AHFLE two plans are created manual and automatic. To find a best plan for the facility a multi attribute decision making (MADM) models are used. In MADM there two types to solve these decision making problems like information aided manual planning and analytic hierarchy planning (AHP).

Marvin A. Arostegui Jr., Sukran N. Kadipasaoglu and Basheer M. Khumawala (2006) compared the types of heuristic methods for facility layout problems (FLP). The mainly used heuristic methods are Tabu Search (TS), Genetic Algorithm (GA) and Simulated Annealing (SA). These methods were done on many types of FLP under different types of conditions like time limited, solution limited and unrestricted conditions. For the test the authors used three problem domains namely capacitated FLP (CFLP), multi period FLP (MPFLP) and multi commodity FLP (MCFLP). After the deep studies the author concluded that the results obtained by GA and SA are dependent on the problem type and the conditions used but TS shows overall good results for all types of conditions and problem types so this technique should be first applied. TS as compared to others yield better results so it should be tried first and also it is easy to implement.

N. Menck et al, (2012) discussed factory planning using the virtual reality (VR) technology. This VR technology provides human computer interface for the purpose of designing, analyzing, planning and optimizing any complex facility layout designs. VR can also help in fixing the problems such as whether the equipment's and machines can be placed at the given area or has no place for those machines. The virtual reality user interface (VRUI) software is used. Use of virtual reality will help in the future problems that can occur while shifting of the plant to the different location.

M. Iqbal and M. S. J Hashmi (2001) did design and analysis of virtual factory layout. Mostly factory layout is done on computer based software like AutoCAD but the drawback in this software is that they give the 2D layout of the factory which is difficult to visualize. To overcome this problem the authors implemented a virtual factory which will give the 3D view of the layout and help in visualizing the layout.

With use of VR setup the planner will be able to view the actual setup of the factory. With the help of VR problems that may occur in future like layout problems; flowpath and safety and material handling can be visualized and changed using techniques to solve problems.

V. Madhusudanan Pillai, Irappa Basappa Hunagund and Krishna k. Krishnan (2011) proposed a robust facility layout for the organizations. Dynamic plant layout problem (DPLP) assumes that the layout will change any time with low cost of relocation and low cost loss while interrupting production and machines that can be easily relocated. A robust design is a single layout that will have low cost of rearrangement and reduce loss of production while relocating. Simulated Annealing is proposed for the problem solving if any occur.

Jaydeep Balakrishnan, Chun-Hung Cheng and Kam-Fai Wong (2003) talked about the facility layout optimization using FACOPT which is user friendly and effective. Many researches are done on facility layout problems. There are some algorithms that can be used to solve facility layout problem but are not very easy to use and can mislead sometimes.

This FACOPT software uses two well-known methods namely simulated annealing and genetic algorithm. The FACOPT software uses data of the various departments to generate the layout then one of two methods is selected to generate the solutions to those layouts. Layout optimization can reduce the production cost. In addition to these methods of optimization Tabu Search method can also be done to find a solution to layout problem.

Vivek deshpande et al.(2016) presented a methodology of designing layout using computerized relative allocation of facilities technique (CRAFT) and automated layout design program (ALDEP). Many organizations want to increase the productivity by changing the layout of the facility. CRAFT is the technique in which some changes are done on the existing layout to increase the productivity while ALDEP technique is used to prepare an entire new layout of the facility. By using the CRAFT and ALDEP techniques there were some significant saving in material handling cost of up to 23%, which contributes in increasing the productivity.

6. DISCUSSION

Based on the literature review done on the facility layout planning and problems associated to the facility layout problems were discussed by many researchers. The main focus of the researchers for facility layout problems were on the heuristics methods for the optimization of the layout. There were many heuristics methods to work on but the best methods were Tabu Search (TS), Genetic Algorithm (GA) and simulated Annealing (SA) that were used. In these heuristic methods Tabu Search was found to be more

effective compared to the Genetic Algorithm and Simulated Annealing. All the results obtained by using TS, GA and SA were dependent upon test done on them and each showed different results but TS obtained most overall good results and should be tried first.

Many researchers also discussed on the planning of the layout done using software's like AutoCAD but it was difficult to visualize the layout so they used different techniques like Virtual Reality (VR), Augmented Reality (AR) to visualize the layout in the real life view. These techniques provide a better planning of layout as the problems that may occur in the future can be visualized and can be solved before final planning. WITNESS software is also used to make a proper layout which uses data of the organization to obtain a proper layout. New techniques like CRAFT and ALDEP also used by some researchers to make a layout in which CRAFT is used to redesign an existing layout while ALDEP is used to create new layout. These techniques the most widely used by the industrial designers which makes the work of designers easy.

7. CONCLUSION

Many organizations look to improve their productivity which can be obtained by optimizing the plant layout. The optimization techniques should be used to obtain these results but many researchers investigated on heuristic methods of optimization like TS, SA and GA. Alongside these techniques virtual reality and augmented reality are other two methods used while designing plant layout. Based on the literature survey many researchers used heuristic methods like tabu search, simulated annealing and genetic algorithm for optimization of layouts. For better results in the future both factory planning and optimizations can be done in one go using human computer interface and heuristic methods to proper and improved facility layout planning. Planning and Pre work of designing of layout and Facility planning is a wide area of study and should be done with taking proper care. Combination of the heuristic methods and designing software have never been done before which will give very good results if applied while planning for facility.

Plant Layout Design of an Assembly Division of the Automobile Company

Vichesha Yardi, Vivek A. Deshpande

Department of Mechanical Engineering

G. H. Patel College of Engineering and Technology, Vallabh Vidhyanagar, Gujarat, India

Abstract: Facility planning is an arrangement of all physical configurations on the plant floor to optimize the best result by utilizing all the available resources in an efficient way. The paper is meant to optimize the new plant layout design of a transmission assembly plant, as it is company's requirement to expand its manufacturing capacity to cope up with the market's increasing demand. The detail literature survey has been carried out to find out the better technique to achieve the goal as mentioned. The data collection and its detail analysis have been conducted to develop the operation sequences. Some construction algorithms are selected and applied to develop layout alternatives and the best layout is selected based on the score optimized and the process sequence. To conclude the findings quantitatively, the frequency analysis is performed and the frequency matrix has been generated to justify that the layout selection based on qualitative analysis is the optimum layout.

Keywords: Systematic Layout Planning, SLP, CORELAP, Automated Layout Design Program, ALDEP, Automobile Industry, plant layout design

1. INTRODUCTION

The management of an automobile company has decided to expand its manufacturing capacity 10 times compare to its present capacity. This decision of the capacity expansion led to the conclusion to assemble the transmission unit in-house. The case study is about developing a new facility layout of transmission assembly line of an automobile company. The objective of the case study is to design a layout by using proper Industrial Engineering (IE) tools by which some of the 7 wastes can be eliminated at the design stage only. The paper explains the techniques and required data collection in the further sections of "Methodology" and "Data Collection". The analysis of the layout is conducted based on both; the qualitative analysis (using REL chart) as well as the quantitative analysis (using Frequency matrix) by using two algorithms: Computerized Layout Planning (CORELAP) & Automated Layout Design Program (ALDEP) and it is discussed further in "Analysis" section. Exact allocation of each facility on available space is described and concluded at the end of the paper.

2. LITERATURE SURVEY

2.1 Facility Planning

The reason behind investing time and resources for the systematic design of plant layout is the integration of the customers's requirement, materials (raw, finished, and in process), and machinery in such a way that all together create a single, well-functioning system. Classification of layout can be done based on the manufacturing system such as fixed layout, product layout, process layout, cellular layout (A Drira, 2007). The fixed product layout is

commonly found in ship or aircraft manufacturing industries which manufacture large size products. Process layout groups facilities with similar functions together. Product layout is used where production volume is high and a low variety of products, whereas in Cellular layout, machines are grouped into cells, to process groups of similar parts.

2.2 Various tools and techniques observed to design an efficient plant layout during literature survey

Systematic Layout Planning is a sequential guideline to the process engineer who is responsible to design a layout and the modified SLP diagram has been presented in figure1 (C S Tak, 2012). There are four stages: 1st is the data collection, 2nd stage is the analysis where the REL chart is developed and the total required space is then calculated. In 3rd stage, two construction algorithms are used to generate the alternatives: CORELAP & ALDEP which are the heuristic approaches to generate new layout. The final stage is the selection of the best layout among all alternatives based on the most suitable score.

Filippo De Carlo (2013) could successfully reduce throughput time by 3.9% and the worker moving time by 15% by using SLP technique. Lean concept along with SLP could reduce 4.15% in throughput time and 24% in workers moving time. The author could reduce the material handling distance by 9.017% by using CORELAP method by aligning the packaging process to operate it efficiently (I Hakim, 2015). Vivek Deshpande and Nitish Patil (2016) have applied ALDEP methodology and achieved the improvement in material handling cost by 23%, which are

in fact 44.75lacs rupees per annum with further benefits of increased productivity.

Fig. 1. Modified SLP diagram

3. METHODOLOGY

The process begins with required data collection which includes Flow process Diagram (FPC), Bill of materials (BOM), annual demand which decides the production rate, product variant, no. of manpower required, no. of workstations and type of material handling equipment required. Secondly, allocation of the facilities following the operation sequence by using some IE techniques like SLP, CORELAP and ALDEP which are applied to develop the alternatives and the optimal layout is selected based on the operation sequence followed and the score obtained. Furthermore, the selected optimal layout is then justified by comparing it with the result of the frequency analysis.

3.1 Data Collection

Figure 2 represents the Flow Process Diagram (FPC) of a transmission assembly line which is an essential data to decide what type of departments should be included in available floor space to design a layout.

Fig. 2. Flow Process Chart (FPC)

After analyzing the FPC, the total no. of required facilities with its space has been optimized and shown in table form in figure 3.

	(dimensions are in meters)			
	Dept.	length	width	Total area
Store	1	35	20	700
Trolley area	2	5	5	25
Transmission (Trans.) Cleaning machine	3	7	2.8	19.6
General purpose cleaning machine (GPCM)	4	6	2.8	16.8
Rear Axle Carrier (RAC) and clutch housing (C/H) cleaning machine	5	4.05	3.1	12.555
Subassembly line	6	22	7	154
main assembly line	7	22	5	110
Millipore area	8	4	7	28
Total				1065.955

	m ²
Available space	1600
Required space	1065.95
Aisle width	426.38
Total required space	1492.33

Space comparison table

Space requirement of each facility

Fig. 3. List of facilities with required space

The aisle width should be at least 40% of total required space which has also been considered and mentioned in the second table of figure 3 (G K Agarwal, 2013).

3.2 REL Chart

REL chart is a group activity and to prepare the same, the opinion from all the heads and engineers has been involved in a project has been considered. It is developed by using 6 relationship indexes called: A-Absolute Important; E-Essential Important; I-Important; O-optional Important; U-Unimportant and X-Undesirable. The final REL chart and reasons for closeness is shown in table form in figure 4.

Department from/To	1	2	3	4	5	6	7	8	
1		A	E	I	I	I	E	U	Closeness rating
2	2		I	I	I	I	U	U	
3	2	2		U	U	U	A	O	
4	2	2			I	E	U	A	
5	2	2				E	U	A	
6	2	2		2	2		A	U	
7	2		1			3		U	
8			1	1	1				
Reason for closeness									

1	Min. distance for min. MH cost
2	Frequency
3	Operations sequence

Reason for closeness

Fig. 4. REL chart

3.3 Layout Generation

3.3.1 ALDEP Algorithm

Selection of the first department to place it on available space is performed randomly and the remaining departments are selected based on closeness rating with the previously placed department. There are total 8 departments and thus total 16 alternatives are generated by considering two directions for the placement and have been represented in figures from figure 5.

Fig. 5. Layout Alternatives by ALDEP method

The weight factors assigned to REL indexes are as follows: A: 4^3 ; E: 4^2 ; I: 4^1 ; O: 4^0 ; U: 0; X: -4^4 . The total score is calculated by summing weight factors of an individual pair and best layout is selected which has the highest score and also the one which follows the operation sequence. Figure 6 shows the total score table of all 16 alternatives with remarks.

No.	Score	Comment
1	396	Optimum, follows operation sequence
2	376	Not optimum
3	388	Follows operation sequence
4	384	Not optimum
5	364	Not optimum
6	380	Not optimum
7	384	Not optimum
8	380	Not optimum

No.	Score	Comment
9	372	Not optimum
10	380	Not optimum
11	304	Not optimum
12	368	Not optimum
13	320	Not optimum
14	380	Not optimum
15	316	Not optimum
16	344	Not optimum

Fig. 6. total Score of each alternative

3.3.2. CORELAP Algorithm

Assign weight factor to each closeness rating assigned to the pairs which are as follow: A-6; E-5; I-4; O-3; U-2; X-1. Figure 7 presents two tables: the first table of the facilities with their total score arranged in descending order and second table helps to decide the allocation of a selected facility with already placed facilities.

	Closeness ratings	Summation of rating	Total	Dept. to be placed	REL index with previously placed dept.	Total Weight Rating
1	A+E+I+I+I+E+U	6+5+4+4+4+5+2	30	7	1	81
6	I+I+U+E+E+A+U	4+4+2+5+5+6+2	28		E	
5	I+I+U+I+E+U+A	4+4+2+4+5+2+6	27	7	2	1
4	I+I+U+I+E+A+U	4+4+2+4+5+6+2	27		U	
2	A+I+I+I+I+U+U	6+4+4+4+4+2+2	26	7	1	82
7	E+U+A+U+U+A+U	5+2+6+2+2+6+2	25		E	
8	U+U+O+A+A+U+U	2+2+4+6+6+2+2	24			
3	E+I+U+U+U+A+O	5+4+2+2+2+6+3	24			
Descending order of the facilities based on total weight score				Options for the placement of facility 7 with the previously placed facilities		

Fig. 7. Weight assignment in CORELAP method

Fig. 8. Optimal layout using CORELAP method

Figure 8 shows the final optimal layout with its score selected by using CORELAP technique. As shown in the first table of figure 7, the dept. no. 1 should be selected and should be placed at the centre point of the layout. The sequence of the placement of the remaining department is based on its highest closeness rating score with the already placed facilities and it is explained in the second table of figure 7. The weight assignment to the closeness rating index of a pair is as follows: A-243; E-81; I-27; O-9; U-1; X-(-729).

3.4 The selection of the layout

The first alternative from the table mentioned in figure 6 and layout from figure 8 are the optimal layout derived by two algorithms. Comparison of both the layouts shows that there will be a requirement of U-shape assembly line if layout developed by using ALDEP is considered. Which will lead to the duplication of MH equipments and the movement of the flow will also become congested. This

leads to the conclusion to select the layout in figure 7 for further design.

Figure 9 represents the proper arrangement of all activities along with aisle width and table13 shows the name of activities allocated on floor space with number indications.

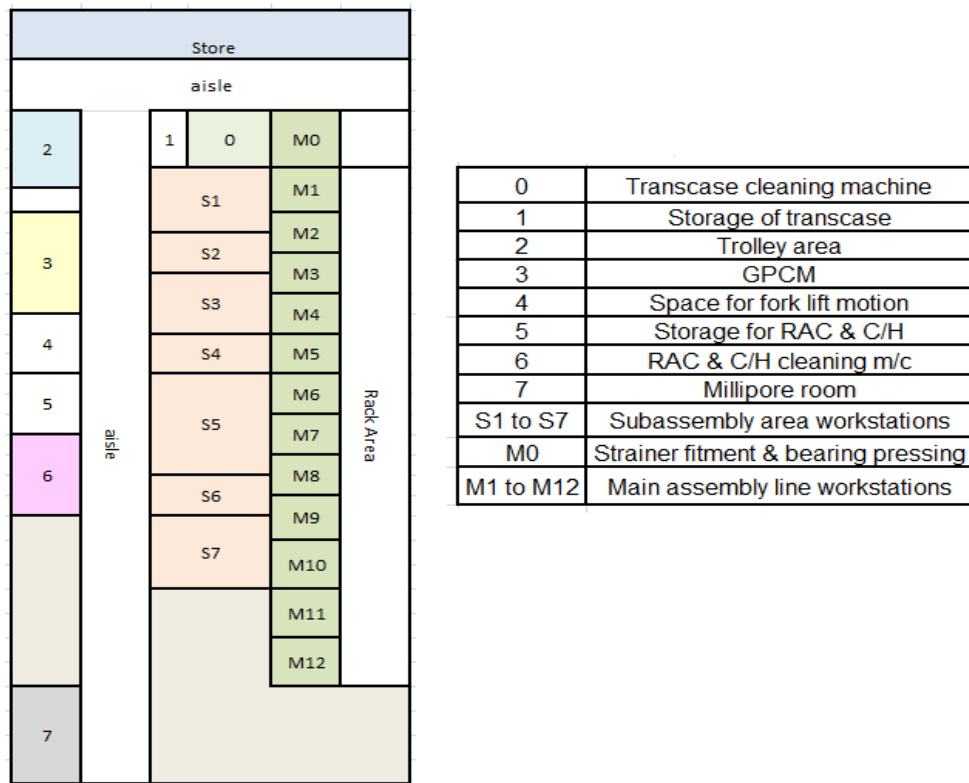

Fig. 9. Detail design of the optimal layout

4. FREQUENCY ANALYSIS

To understand the frequency between departments, one needs to understand what type of material and with what quantity need to be moved to follow operation sequence. To move the material from store to cleaning machine, kits are used and moved in hand trolley. These kits are designed

according to the dimensions of the material which needs to be moved from store area to general purpose cleaning machine and then from cleaning machine to subassembly area. One trolley carried one kit only. Considering this limitation, the total frequency between these two pairs of departments have been analyzed and identified.

TABLE 1: Frequency analysis

from/To	1	2	3	4	5	6	7	8
1				165		2	2	
2	165							
3							50	1/7
4						165		1/7
5						10		1/7
6		165					600	
7								
8								

Furthermore to supply empty transmission case and rear axle carrier from dock area to respective cleaning machine also been analyzed by counting no. of a unit on a palate and calculating the total no. of frequency between these two pairs of departments have been analyzed and mentioned in table1. Table 1 shows the frequency analysis per shift considering 50units per day.

It is quantitative analysis of the department pairs which justifies the placement of adjacent departments. As described in table 1 pairs such as trolley area & store, store & GPCM, transmission cleaning machine & main assembly line, GPCM & subassembly area and main assembly line & subassembly area are allocated next to each other in a layout.

5. RESULT DISCUSSION & CONCLUSION

The construction algorithms like ALDEP and CORELAP are applied here to develop the layout alternatives whereas Systematic Layout Planning method is used here to design a layout systematically. The Layout is optimized by applying IE techniques to eliminate some of the wastes such as unnecessary motions of resources, rework and delay. The best optimized layout is selected in this case as shown in figure 9.

The frequency matrix observation justifies the placements of the activity pair placement adjacent to each other as shown in table1.

It can be concluded that the layout design optimized is the best solution for the resources allocation on plant floor by observing and comparing the final layout design with frequency matrix as it is derived by applying IE techniques which considers all the wastes elimination at designing stage only. Thus the optimized design gives the best result which is justified.

Optimization of Facility Layout for Improvement in Productivity

Vaibhav Nyati, M. D. Jaybhaye, Vicky Sardar

Department of Production Engineering and Industrial Management,
College of Engineering, Pune, Maharashtra, India

Abstract: Plant layout or a facility layout is the design and installation of systems of men, materials and equipment. It is the joint determination of the locations, sizes and configurations of multiple activities within a facility. It illustrates a floor plan for arranging the desired machinery and equipment of a plant, established or contemplated, permitting the easiest flow of materials. It strives to achieve lowest cost with minimum material handling, in processing the product from the receipt of raw material to the dispatch of the finished product. The objective of this research is to study the existing plant layout of manufacturing unit and improve it using Systematic Layout Planning (SLP) theory for better plant area utilization and increased productivity. It indirectly reduces the throughput time. In this research, different types of Lean Manufacturing tools and techniques are used so that its ultimate effect will be on productivity and quality.

Keywords: Facility Layout, material handling, Systematic Layout Planning (SLP)

1. INTRODUCTION

ABC Industries is one of the prominent Aluminium Die Casting foundry in Pune region. ABC Industries has mastered the various manufacturing processes like High Pressure Die Casting, Gravity Die Casting, Die Casting Tool Manufacturing and Auto-components. It manufactures critical Engine and Transmission auto parts along with non-auto Die Casting parts for global OEMs. The combination of world-class facility and tie-up with Global Technology players has catapulted ABC Industries as "Best Die Casting Foundry "

2. LITERATURE REVIEW

The analysis of facility design such as layout and material handling system is very important in a manufacturing industry. Proper analysis of existing layout design could improve the performance of production line. It also helps in decreasing bottleneck rate, minimize material handling cost, thereby reducing idle time and enhancing the efficiency and utilization of resources. (C.N.Kulkarni, Dr. M.I.Talib, Dr. R.S. Jahagirdar, 2013). The productivity improvement is made through modification of shop floor layout which supports the multi machine manning and streamlining the material flow in between the machines. The cycle time analysis and part flow analysis is carried out to group the machines, which look more in detail on bottleneck processes. The analysis on machine utilization and layout of machinery is made to enhance the machining capacity of the shop floor. The selection of the best labour allocation strategies should simultaneously consider production output, lead times, and the amount of work in process inventories in the system. (Karthik T, Sentikumar M, 2012). The facility layout design defines how to organize, locate,

and distribute the equipment and support activities in a manufacturing facility to accomplish minimization of overall production time, maximization of operational efficiency, growth of revenue and maximization of factory output in conformance with production and strategic goals. (Md. Riyad Hossain, Md. KamruzzamanRasel, SubnataTalapatra, 2014). To increase the productivity, we have either to increase the speed or decrease the distance of the material path.

The distances are given by distances through which the material must move distances equipment must move, distances operators must move, types of handling equipment. (S. M. Kadane, S. G. Bhatwadekar, 2011). Facility planning is concerned with the design, layout, and accommodation of people, machines and activities of a system or enterprise within a physical spatial environment. (Garcia, A.D., Smith, McG., 2008). The facility layout design determines how to arrange, locate, and distribute the equipment and support services in a manufacturing facility to achieve minimization of overall production time, maximization of operational and arrangement flexibility, maximization of turnover of work-in process (WIP) and maximization of factory output in conformance with production schedules. (Huang, 2003). In manufacturing systems, the three main types of layout are product layout, process layout, and group layout, which is further categorized into flow line, cell, and centre (Askin R. G., Standridge, 1993). The product layout (flow shop) is associated with high volume production and low product variety, while process layout (job shop) is associated with low-volume production and high product variety. (Hesen, Renders, Rooda., 2001)

3. EMPIRICAL STUDY

In this section, an empirical study is presented to illustrate the application of facility layout for improving the productivity followed by String Diagram method.

3.1 Problem Statement

Causes that contributed to the need for a re-layout were identified as:

- Congestion and bad utilization of space.
- Excessive stock in process at the facility.
- Long distances in the work flow process.
- Simultaneous bottle necks and workstations with idle time.
- Labour anxiety and discomfort.
- Accidents at the facility.
- Difficulty in controlling operations and personnel.

In the secondary phase of this research, proper material handling techniques are defined to prevent the accidents and damages. This part will be focusing on design of new trolleys, zero pallet on the floor.

3.2 Methodology

Company focuses mainly to improve the productivity of plant. The research follows a systematic layout planning

(SLP) approach to improve existing layout of the ABC Industries. The detailed study of the plant layout such as operation process chart, flow of material and activity relationship chart was investigated. Final layout was selected by installation of new machine with effective utilization of area to improve productivity.

Process Flow for Systematic Facility Layout:

1. Streamline the flow of materials through the plant.
2. Facilitate the manufacturing process.
3. Maintain high turnover of in-process inventory.
4. Minimize materials handling and cost.
5. Effective utilization of men, equipment and space.
6. Make effective utilization of cubic space.
7. Provide for employee convenience, safety and comfort.
8. Minimize overall production time.
9. Maintain flexibility of arrangement and operation.
10. Facilitate the organizational structure.

There are more than 50 types of parts which are manufactured in each month at ABC Industries. All these parts belong to different part families. Every part goes through different processes as per the customer requirement. All parts are passed through High Pressure Die Casting Process.

Sample size of 15 parts is taken into consideration for this study. This sample size was decided based on Monthly Production Schedule-June 2017. The Pareto chart of this analysis is as shown below:

Fig. 1. Pareto chart for sample size selection

From the above Pareto Chart, few parts were selected based on their sales quantity. The result was concluded that the parts till VECV PART NO.2 carries the 80% of the total quantity. The flow of all these parts was studied with objective of minimizing the distance travelled and transportation time. Material flow analysis for one part (Cummins Part No.2) is illustrated in table no. 1. The part was selected based on its criticality of material flow through whole layout.

ILLUSTRATION: CUMMINS PART NO.2

2) Existing Material Flow:

The standard sequence of processes followed by ABC Industries is illustrated in Figure No. 3.

Fig. 2. Process Flow Diagram

- Melting: Alloy-AlSi9Cu3 is melted in the oil-fired furnace at the temperature of 660°C.
- High Pressure Die Casting: In die casting liquid metal is injected into a die of the exact shape in which, under pressure, it solidifies.
- Riser Break: A riser, also known as a feeder, is a reservoir built into a metal casting mould to prevent cavities due to shrinkage. This part of casting is removed using the cutting system.
- Fettling: It is the process of removing the unwanted metal e.g. flashings, riser, heat check mark etc. It includes the processes like punching, chipping, filing, grinding etc.
- Machining: It's a broad term used to describe removal of material from a workpiece, it covers several processes such as cutting, milling, drilling etc.
- Leak Testing: This process used to ensure quality control which helps to verify strengths of the product and guarantee customer safety.
- Washing: The viscous oil which is used in leak testing and the coolant used in machining is washed by this process.
- Inspection: The process of verifying the desired parameters meet the requirements.

To find out the distance travelled by each part, the part movement was plotted on string diagram and the total distance travelled was calculated by Euclidean Distance Method as shown in Figure No. 4

Fig. 3. String Diagram of Cummins Part No.2 (Existing Layout)

3) Distance Travelled:

The start and end processes were considered as High Pressure Die Casting (HPDC) Process and dispatch respectively. The distance travelled from melting process to HPDC was not considered due to some handling limitations.

TABLE 2: Distance Travelled and Transportation Time recorded (existing layout)

CUMMINS PART NO. 2		
From-To String	Distance travelled in meters	Transportation Time Per Part in sec
01 to 02	7	60
02 to 03	90	20
03 to 04	106	40
04 to 05	40.5	60

Cummins Mount Gen	428.75	243.75	43.15

5. CONCLUSION

After the execution and analysis, it was found that the total distance travelled per part was reduced by 50%. New layout eliminated the backtracking of material flow, reduced material handling which ultimately resulted in less WIP as compared with the existing layout. Significant reduction in the manpower required for material handling was observed in the proposed layout. Implementation of the proposed layout prevented the amount of rework thereby reducing overall production time. New layout provides the high flexibility in arrangements and operations which directly

minimizes the investment on equipment. Due to effective utilization of the facilities, the idle time of machines was comparatively reduced than earlier scenario.

Abstract: Facility planning is anxious with the design/layout/arrangement of people/machines/activities of a system within a physical special environment. Facility planning is imperative in a manufacturing process/design field. There is 20% to 50% of the total costs of manufacturing is related to material handling and this cost can be minimize by applying effective facility planning in an organization. Various factors like decrease bottleneck operations, minimize the material handling cost, reduces idle/working time of machine, effective utilization of labor/equipment and space in the organization. The objective of this research is to improve the productivity by modifying in the plant layout /arrangement of a heavy loaded vehicle manufacturing company based on the systematic layout planning pattern theory (SLP) for improvement in productivity. Researcher used different tool like operation process chart, flow process of material/activity relationship for the present plant layout. Outcome of research shows significantly improvement in distance/ time used by operator and saving in floor space also.

Keywords: Material Flow, Production, systematic layout planning, Plant Layout.

1. INTRODUCTION

In today's world it is important to meet customers demand with excellent quality in product. It can be achieving by improving available resources like employees/machines and other amenities. Plant layout improvement is the tool by implementing it industrial productivities enhanced. In current development Plant layout design has become a necessary part of today's world. For creating the most effective plant layout researcher has focused on materials/machines/equipment, and other process.

2. LITERATURE

In this by Anucha Watanapa [1] suggested improvement in plant layout by, improving material flow operation, disassembly surface finishing and inspection sections. W. Wiyaratn and A. Watanapa [2] talked about manufacturing industry plant layout. In this research various sections of layout like material flow, operation flow process chart has been focused. By using systematic layout planning (SLP) method researcher proposed new plant layout. In this paper of R. Jayachitra and P. S. S. Prasad [3] Genetic algorithm (GA) tools used for design of cellular layout. WITNESS 2006 simulation software is also used. Uttapol Smutkupt, and Sakapoj Wimonkasame [4] has proposed layout design in improvement in total time, waiting time etc. with the help of Microsoft Visual Basic software.

3. PLANT LAYOUT PLANNING

In table no 1 engine assembly station facility is shown. In this handling capacity of per trolley/day and quantity for per day is shown.

Fig. 1. Flow process chart of activity conducted in current research

4. ANALYSIS PLANT LAYOUT

In the current research plants various department/process is focused i.e. inspection section, machine/fabrication shop, surface finishing department and raw material storage section. Researchers found there is a improvement needed in flow/ storage of raw material department. Raw material storage is away from the plant area. By modification in this location material handling could be improved.

For the feeding of engine and transmission from the storage area to station separate trolleys are used so that operators have to move more distance for engine and transmission. There is no common tool kit for keeping the tool which is frequently used during operation so that more repetitive tool motions. There is 8 engine transmission inventory which

occupied more floor space. Location of rack and kit trolley is not proper and it is not in reach, so operators have to travel more distance to pick the material.

Fig. 2. Existing Layout

There are three stages for tightening process to set the torque of engine transmission 12 bolt, no provision of advance tool for deletion of 3 stage tightening of bolt (Loose, Impact Wrench, manual torque wrench).

In the current research vibrator compactor, loader/backhoe industry is considered. The original layout of Engine sub assembly station is shown in figure 2. Handling capacity per trolley and required quantity per shown in Table 1.

TABLE 1: Engine assembly station facility			
Item namex	Handling capacity per trolley	Required quantity per day	
Engine + Transmis sion Trolley	1 item	8 item	
Engine Feeding Trolley	1 item	4 item	
Transmis sion Feeding Trolley	1 item	4 item	
Material Rack	9 item	5 item	
Kit Trolley	9 item	3 item	

5. METHODOLOGY

In current research, proposed layout is design on the basis of flow process chart (man type) (fig. 3) of engine sub assembly.

TABLE 2: Flow process chart (man type) for existing layout

ENGINE ASSEMBLY

OPERATION	○	→	□	▽	Distance in Meter	Time Second
pick engine lifting sling						
move 8 steps with crane to engine line storage					5.6	7.33
move 15 steps to get engine subassembly trolley					10.5	13.75
back to engine line storage					10.5	13.75
hooking crane to engine						
pull engine s/a trolley to E1 stn(8 steps)					5.6	7.33
move 3 steps to rack4					2.1	2.75
pick bolts(4 nos.) 613-08025(8*25)						
move to rack5					2.1	2.75
move to tool post 1(3 steps)					2.1	2.75
position it on bolts to tight them						

move 3 steps to tool post 1				2.1	2.75
move back to stn(3 steps)				2.1	2.75
position torque wrench on fan mtg bolt 1 by 1 with 20 deg rotation					
place all tools to tp1				2.1	2.75
Total				44.8 m	58.66 sec

For optimum space utilization and reduce travelling distance load score method is used for layout analysis. In this method in step1 matrix made based on department/machines for load/frequency. In step 2 distance matrix is made for current layout. Finally total matrix is made. This matrix help in calculating load distance score for engine assembly. This lead to fabrication of flow process chart (Man type) process chart shown in (fig. 3).

Fig. 3. Propose layout

Engine is shifted between parts and transmission Parts location is spited in two stations for smooth flow of process by applying this total distance travelled minimized

6. CONCLUSION

After applying Industrial Engineering tool, the productivity of engine sub assembly line boosted. There are some outcome of research Floor space has saved by 38.36%, total distance travelled reduce by 58.75%, By flow process chart 50% station inventory has been reduced and 58.33% material handling time is also saved.

Abstract: This Research paper a Multi facility location problem with single Relocation opportunities is investigated. The weight Associated with each demand point is a known function of time. We take Euclidean distances and Rectilinear, squared Euclidean. Relocations can take place at predetermined times the objective are function is to be minimize the total location and relocation costs. By use of algorithm which can find the optimal location, relocation times and the total cost, for all three types of distance measurements and various weight functions, is developed by Locations are found using constant weights and relocation time are the solution to a Dynamic Programming or Binary Integer Programming (BIP) model. The time horizon can be finite or infinite.

Keywords: Discrete- horizon, Relocation, Time dependent, Location, weight function

1. INTRODUCTION

Dynamic facility location models can be considered to be extensions of the conventional (single-period or static) models as they include time varying demand. Most of the models developed in the literature for dynamic location problems assume that facilities can be relocated between periods in response to changes in demand. There are associated relocation costs for changing the location of facilities between periods, which can represent the initial investment for establishing new facilities and the cost savings for the closure of Existing facility.

Most of the continuous and discrete static location problems are known to be NP hard. Dynamic location problems are at least as difficult to solve as the static problems due to the additional consideration of time. However, the algorithms and solution approaches developed for static location problems can be adapted to solve the dynamic problems. Throughout this section we review the literature in dynamic facility location. We separate the dynamic models into continuous and discrete location models

Facility location has an important role because the site selection directly relates with the warehouse systems, inventory control and handling, customers and suppliers. A good location gives a strategic advantage against competitors. To give service to potential customers better by short distances stated by Jayaraman and Vaidyanathan, 1998. As locating more outlets a company enhances its accessibility and hence improves its overall customer service. John Mills, 2004 said that the determination of a

facility location is a well-known phenomenon in operational research area. The facility location means the placement of a planned facility with regard to other facilities according to some constraints. There are both quantitative and qualitative methods applied for the facility location problem. Chen, 2001

2. LITERATURE SURVEY

Facility location is a strategic management decision. Such a decision is usually made applying the current conditions such as population, infrastructure, service requirements and others Kim et al., 2000 Common location models deal with single and multiple facility location, covering p-median, p-center problems, their Applications and extensions. Many of these problems can be very difficult to solve. It is not surprising that so much work has focused on stochastic and deterministic problem formulations. While such formulations are reasonable research topics, they do not capture many of the characteristics of real-world location problems.

The strategic nature of facility location problems requires that models consider some Aspect of future uncertainty. Since the investment required by location of planning of lay out. The problem of facility location truly involves an extended planning horizon. Decision makers must not only select locations which will effectively serve changing demand over time, but must also consider the timing of facility expansions and relocations over the long term . Ficko, 2004 a series of static deterministic optimal solutions to solve the dynamic problem of locating a single facility

warehouse so as to maximize profits over a finite planning horizon. For each period in the specified horizon, he solved for the optimal warehouse location, establishing a set of potential “good” location sites. Dynamic programming is then used to determine the best schedule for opening a subset of these sites as an “optimal” location and relocation strategy for the planning period. [Tompkins, 1996].

This method finds the RI best solutions in each period t through an iterative procedure of solving integer programs with Benders’ decomposition. The number of solutions (R_i) varies by period and is found through bounding the overall optimal solution value. The expanded set of potential location sites for each period is then used in a dynamic program to determine an optimal location and relocation strategy. Note that both of these papers allow for frequent facility relocation Heragu, 1990. This approach was later found to be sub-optimal, but neither considers construction time or cost of relocation in the objective function. Extended the single facility location problem to a model where the facility location could change in a given time interval. In his paper, Wesolowsky presented an Algorithm for calculating the optimal location when the cost. [Ficko et al, 2004].

(Jain et. al, 2013) the results for a single facility dynamic location relocation problem these results are helpful in finding optimal initial decisions for the infinite horizon problem by using information only for a finite horizon. The proposed a forward algorithm for the solution of a single facility dynamic location/relocation problem. In their paper, the problem is reformulated in terms of a shortest path problem in an acyclic network and provides a condition for the existence of a finite forecast horizon for obtaining an optimal initial decision. (Garcia, 2013; Radicchio, 1970)

Amine Drira, 1975 defines in his review, different types of facility layout problems and has discussed various problem formulation methods the different facility problem solving techniques with more Emphasis on dynamic facility layout problems. He has derived a rough tree structure to present an idea of different considerations while developing a plant layout. The Reviewed about techniques that are used to optimize single objective functions and evaluated various variety of space allocation problems and uses of different algorithm to solve these space allocation problems with detailed review of facility problems/space allocation problem. The authors also discussed limitations of different algorithms and research gaps in automation of facility layout solving tools which are commercially available, SaChine, 2010.

The review in multi criterion facility location problems and has categorized multi criterion facility problems in to three categories, which are bi-objective, multiobjective and multi-attribute. The authors also discussed about methodology to be used to solve these categories problems

and briefly mentioned about criteria’s that are used in literature to solve facility location problems. (R.E. Love et al., 1975) A study on the cellular layout, cellular manufacturing system has been done and a case study has also been done to illustrate the benefits of cellular layouts .[Heragu, 1980]. The travel diagram technique could be used to minimize wastes of maintenance time, manpower and money and to generate higher profits for the same work from the same resources. [Jain, 2013]. Systematic Layout Planning (SLP) procedure has been used to modify the plant location

The Plant layout in cellular manufacturing firm to improve the productivity of the firm. [Garcia, 2013]. An Extension of the CRAFT algorithm that aimed to solve complex layout problems has been developed and the results were compared with that obtained from literature. [Tompkins et al., 1996]. Location models can also be classified as deterministic or stochastic. Deterministic models assume demand and other data to be known with certainty. Stochastic models incorporate information on the uncertainty of data and aim to determine solutions that perform well under all possible data realizations, according to an objective derived from the objective of the deterministic version of the model, such as maximizing the expected performance or minimizing the worst-case performance

3. METHODOLOGY

The minimum problem consists of locating a Dynamic facility in the plane with the aim of minimizing the sum of the weighted distances (the maximum weighted distance) to m given points. We present two solution methods for generalized versions of these problems in which.

- i) Location is restricted to the union of a finite number of convex polygons; (ii) distances are approximated by norms that may differ with the given points; and (iii) transportation costs are increasing and continuous functions of distance. Computational experience is described
- ii) The objective of the facility. Whether planning a new facility or the improvement of an Existing facility, it is essential that the product to be produced or service to be provided be specified quantitatively. Volumes or levels of activity are to be identified whenever possible. The company under study is concentrating on the rubberized coir mattress production with annual Installed capacity problems that hinder the smooth material flow and it has also been observed that there is a lack of scientific layout planning.

The Euclidean distance between point’s p and q is the length of the line segment. In Cartesian coordinates, if $p = (p_1, p_2, p_n)$ and $q = (q_1, q_2, a_n)$ are two points in Euclidean distance n space, then the distance from p to q is given by

The Euclidean norm measures the distance of a point to the origin of Euclidean space:

The last equation involves the dot product. This is the length of p, when regarded as a Euclidean vector from the origin.

$$f(x, y) = \sum_{i=1}^m w_i [(x - a_i)^2 + (y - b_i)^2]^{1/2}$$

We use the following notation:

X= (x, y)

location of the new facility

P= (a_i, b_i) location of existing machines, i=1, 2, 3m

W_i "weight" associated with maintenance hours and distance

Between Existing facility & machine i=1, 2, 3

The plant was visited for collecting the data. The manufacturing of this component is done by Functional or process manufacturing processlocation, stretching a giant

rubber band around all the pegs, and releasing the rubber band.

The region that the rubber band encloses is known as the convex hull of the existing facility locations. Any optimal solution to the location problem will be inside the convex hull, as the knot representing the optimal new dynamic facility location would never go into Equilibrium outside the convex hull. Facility planning determines how an activity's tangible fixed assets best support achieving the activity's objective. This includes activities such as facilities location, facilities design, facilities layout, or plant layout.

A Dynamic or adaptive strategy will have several time windows each one period long, and a flexible strategy will choose the time windows to minimize the total cost and includes robust and dynamic strategies as special cases where they are appropriate. The robust machine layout sub problem is represented with an integer programming formulation. Its objective function includes both material handling and machine rearrangement cost.

Data from manufacturing industry

	Existing facility Center			Proposed facility Center		
Sr no	Actual distance from facility Centre	Total maintenance in hour(1 year)	Distance in sq.turns=(2x actual distance x total maintenance(in hours)	Actual distance from facility Centre	Total maintenance in hours(1 year)	Distance in sq. Turns= 2xactual distance total maintenance (in hours)

4. DYNAMIC FACILITY LOCATION PROBLEM

Facility planning determines how an activity's tangible Fixed asset best support achieving the activity's objective. The optimum allocation of space to the components of the system is the main aim in developing a layout for a system

producing goods or services. Basically, facility planning means to determine the best arrangement of facilities and equipment in such way that it is capable of satisfying anticipated demand (quantity, quality, and timing) at lowest cost. The facilities that are planned today must help an organization to achieve Supply Chain Excellence. Supply

Chain Excellence is a process with six steps or levels. These steps are Business as Usual, Link Excellence, visibility, collaboration, Synthesis and Velocity. Business as standard works as when a company works hard to maximize its individual functions. The goal of individual department, such as finance, marketing, sales, purchasing, information technology, research and development, Manufacturing, distribution and human Resources is to be the best department in the company. Organizational effectiveness is not the Emphasis. Each organizational element attempts to function level

5. RESULT & DISCUSSION

- Analysis of optimum facility location of Maintenance shop by using Euclidean model. Comparison between existing and new location is carried out.
- The facility of common facilities has also contributed in Enhancement of availability of plant equipments.
- I have finally proposed the location that gives us the optimum maintenance travel time for maintenance work.

With the help of Facility Location Planning Tool (Euclidean with minisum location method) we find out the optimum location for new Facility center of co-ordinates From new location Net savings in distance traveled (in meters)

Saving Maintenance Traveling Time (Distance) in percentage % =	1.03%
Net Saving Travelling Distance in percentage % =	24.6

6. CONCLUSION

- Meet the economic demand: minimize investment in equipment and material handling cost.
- Meet the requirement of product design and volume.

Meet the requirement of process equipment and capacity: minimize overall production time; maintain flexibility of arrangement and operation; minimize variation in types of material handling equipment; facilitate the manufacturing process. The algorithm generates the optimal relocation times, and the optimal location of the facility between two consecutive relocations, such that the total location cost is minimized.

- Reduced inventory in process.
- Safe and proper material handling.
- Optimized use of service facilities
- Reduce the maintenance time

Systematic Layout Planning (SLP) of S101 Engine Plant

Jayesh Gujar, Mahesh Nimbalkar

Mahindra and Mahindra, Pune, Maharashtra, India

Abstract: This paper presents an analysis on a production shop floor layout of S101 Engine manufacturing set up and the application of a systematic layout planning (SLP) procedure, as an approach to solve the production shop floor layout problem.

Major manufacturing facilities required for S101 engine are Engine Head and block machining, Engine Assembly and Engine Testing. Total area requirement for S101 Engine plant was 21, 000 Sq. Meter as against 17, 000 Sq. Meter available area in MHEPL plant. The total area was optimized using systematic layout planning technique. P-Q analysis, relationship diagram, alternative evaluation tools were used from SLP for problem solving. The relationship between machines, operation activities, service departments and material flow are used to determine the optimal location of each machine and service departments. SLP technique has been employed to design the multiple alternatives of production shop floor layouts and compare the performance between new layouts in terms of material flow distance, traveling time, etc. Lean approach used to design total material flow, in process inventory and brought out part material storage. An improvement scheme is proposed after analyzing PFEP (Plan for every part) and material flow. This paper focus on effective use of PFEP in systematic layout planning. Remaining floor space deficit was fulfilled by effective use of MHEPL existing plant area and optimum use of exiting service departments. The alternative layouts were developed based on minimum distance traveled between each machine. It improved the layout by reduced total movement traveled in production for material handling. The measurements covered the actual sizes of the layout and machines, activities between machining cell, assembly and testing, distance between them, and material flow between all manufacturing departments in the company. The proposed procedure is illustrated to be a viable approach for solving production shop floor layout design problem through a real-world case study. As a result of successful implementation of SLP, effective utilization of MHEPL assets and manpower achieved. Scope for further expansion is also kept for future variants of engines. 3, 237 Sq. Meter storage area proposed against earlier requirement of 4979 Sq. Meter (34% optimization).

1. INTRODUCTION

With rapid increasing of demand in production, industrial factories need to increase their potentials in production and effectiveness to compete against their competitors. At the same time, the production process needs to be equipped with the ability to have lower cost with higher effectiveness. Therefore, the way to solve the problem about the production is very important. There are many ways i.e. quality control (QC), total quality management (TQM), standard time, plant layout to solve the problems concerning productivity.

According to the many researchers plant layout is one way to reduce the cost of manufacturing and increase the productivity. Also increases good workflow in production route. This research describes original plant layout, material flow analysis, which includes area and distance between operation A and B. MHEPL plant was selected for laying down new facilities required for S101 engine manifesting. The basic industrial layout planning is applied to systematic layout planning (SLP) method in which showed step-by-step of plant design from input data and activities to evaluation of plant layout. This method provides the new

plant layout that improves the process flow through the plant, and help to optimize space in plant.

2. PROCEDURE FOR PLANT LAYOUT PLANNING

Detailed process flow diagram prepared from store to dispatch of the engines. End to end process was mapped along with support/service department requirement. The data were collected and the number of tools/ equipment for manufacturing was counted in terms of the direction for raw materials and product. The operation process chart, flow of material and activity relationship chart have been used in analysis. The problem of the plant was determined and analyzed through SLP method to plan the relationship between the equipments and area. The framework of SLP is shown in Fig. 1. Based on the data such as product, quantity, route, support, time and relationships between material flow from –to chart and activity relation chart are displayed. From the material flow and relationship activity in production, the relation between each department can be observed. Then the results were drawn through the comparison between the layout options.

Flow of Material

Basic Flow of material is explained as below:

Fig. 3. Block diagram of Systematic Layout Planning technique

SPACE REQUIREMENT

SPACE REQUIREMENT FOR MACHINING LINE

Space or Area requirement of Machining line is calculated as per following formula

$$\text{Total Area Requirement} = \text{Length of Machining Line} \times \text{Width of Machining Line}$$

Total Length of Machining Line=

$$\left[\sum_{y=1}^{y=n} Ay + 1.5 \times Xn \right]$$

Width of Machining Line=

$$[Max(Bzn) + 1.5]$$

Hence,

Total Area Requirement

$$= \left[\sum_{y=1}^{y=n} Ay + 1.5 \times Xn \right] \times [Max(Bzn) + 1.5]$$

Where, Xn= No. of Machines, Ay= Machine Width, B_z= Machine Length

1.5 is minimum distance need to keep on machine side for machine maintenance purpose

*Inventory to be added as per process requirement between two machines

Space requirement for Store

For Store area calculation 'Planning For Each Part' (PFEP) sheet is effective tool. In this Store is divided in to three stages-

On Floor Storage-

It includes Cylinder Head, Cylinder Block, flywheel etc.

$$\text{Area required Part Storage on Floor} = \frac{[(L \times W) \times NP]}{SL}$$

Where, L = Length of Primary Pack, W = Width of Primary Pack, NP = No. of Packs required as per inventory norms,

SL = Staking Levels for Part Storage

No. of Packs required as per inventory norm is calculated as below-

$$NP = \frac{\text{No. of parts required to keep as per inventory norms}}{\text{No. of parts per primary pack}}$$

High Bay(HB) Rack Storage-

It includes A & B Class Items

$$\text{Area required for part storage on HB Rack} = N_{HB} \times A_{HB}$$

Where,

N_{HB} = No. of High Bay Rack Modules required

A_{HB} = Area required for one High Bay Rack Module

Area occupied by one High Bay Rack Module is (Length=2.5meter X Width=2.6meter) 6.5sq.meter

In one High Bay Rack Module, there are eight plastic pallet locations. Capacity of one pallet location is (1.2M*1M*1.5M) 1.8cubic meter

For Calculating No. of High Bay Rack Modules required (N_{HB}), we need to calculate total no. of pallet locations required to store total no. of primary packs.

$$N_{HB} = \frac{\text{Number of Pallet Locations Required}}{8}$$

No. of pallet locations required for one parts are calculated as given below:

$$= \frac{\text{Volume of one primary pack} * NP}{\text{Capacity of one pallet location}}$$

Where,

NP = No. of Packs required as per inventory norms

$$NP = \frac{\text{No. of parts required to keep as per inventory norms}}{\text{No. of parts per primary pack}}$$

Market Place Rack Storage-

It includes C & D category parts.

Area required for part storage on MP Rack= $N_{MP} * A_{MP}$

Where, N_{MP} = No. of Market Place Rack Modules required,
 A_{MP} = Area required for one Market Place Rack Module

Area occupied by one Market Place Rack Module is (Length=2meter X Width=1.3 meter) 2.6sq.meter

As C & D Class parts will come in various packaging sizes, to avoid complexity in calculation, we need to take average packaging size. After Studying PFEP average size of packaging is taken as 0.6meter x 0.4meter x 0.22 meter, which is near to plastic crate size. One Market Place Rack capacity is standardize for 24 plastic crate of above size. Therefore Total number of market place racks required are calculated as given below:

No. of Market Place Racks Module

$$N_{MP} = \frac{\text{No. of plastic crates required}}{24}$$

No. of plastic crates required = No. of Packs required as per inventory norms (NP)

$$\text{Hence, } N_{MP} = \frac{NP}{24}$$

Where, NP = No. of Packs required as per inventory norms

$$NP = \frac{\text{No. of parts required to keep as per inventory norms}}{\text{No. of parts per primary pack}}$$

Advantages of Plan For Every Part (PFEP) for Area Calculations:

With the help of above calculation we have completed PEPF for each project. It helped in following:

1. Total area required for each project
2. Storage location identification for each and every part.
3. Storage facility requirement for every project
4. Material handling equipment requirement
5. Flow of material inside plant.
6. Help in detailed calculation for utilization of each resource in stores
7. Material scheduling and controlling

PFEP result after detailed calculation is given below:

TABLE 1: Area Calculation for Stores

Sr. No.	Facility	Summary of PEEP For S101	Empty Storage Area @ 25%	Area For Variants @ 20%	Total Area
1	On floor	461	115	115	691
2	Market Place Rack	714	179	179	1072
3	High bay rack	983	246	246	1475
Total area in Sq Meter					3237

Earlier area requirement for S101 store was 4979 Sq. Meter. Final area requirement was 3237 Sq. Meter. We have achieved 34% storage area reduction through detailed calculation of PFEP

Alternative Layout Plan evaluation

There layout options were prepared considering above space calculation and Flow analysis.

Number of service department and operating department are summarized in table given below:

TABLE 2: List of MHEPL S101 Engine plant Department

Sr No	Department	Group number
1	Assembly Line and Testing	1
2	Head line And Block Line	2
3	Store	3
4	Engine PDI and Dispatch	4
5	Engine assembly and testing Rework room	5
6	Incoming inspection area	6
7	Rejection area	7
8	Equipment charging area	8
9	Warranty area	9

Total Score			154	106	199

Layout option number 3 selected for implementation of S101 Engine manufacturing facilities.

### 3. CONCLUSION

1. Systematic layout planning (SLP) technique helps in decision making for best feasible layout selection
2. SLP follows structured and analytic process
3. Optimum Storage space requirement can be calculated using SLP

4. SLP helps in material control and scheduling
5. SLP focus on least material handling in plant

# Synthesis and Evaluation of N/TiO₂ Nanoparticles for the Photocatalytic Degradation of Methylene Blue

R. Singh, S. Dutta

Department of Chemical Engineering  
Indian Institute of Technology, Dhanbad, Jharkhand, India

**Abstract:** The N/TiO₂ photocatalyst was prepared by ultra-sonication method for achieving enhanced visible light response. UV-Visible spectroscopy, field emission scanning electron microscopy and energy dispersive studies were carried out to characterise prepared N/TiO₂ nanoparticles. Compared with pure TiO₂, the N/TiO₂ photocatalyst exhibits red-shifts with improved light absorption capacity. Scanning electron microscopic observations reveal almost spherical morphology with relatively uniform sizes. The photocatalytic activity of prepared N/TiO₂ photocatalyst was evaluated by photo degradation of Methylene Blue (MB) under simulated solar radiation. The increased dye degradation efficiency of N/TiO₂ photocatalyst may be attributed to the enhanced visible light absorption for photoexcitation and charge separation efficiency.

**Keywords:** semiconductor, nanoparticles, ultra-sonication, heterogeneous photocatalysis, visible light

## 1. INTRODUCTION

Transition metal oxides are most commonly used for photocatalytic applications (Marschall and Wang, 2014). TiO₂ is a wide band gap non-toxic semiconductor photocatalyst with high chemical stability and low cost. However, pure TiO₂ limits its application to the UV part of the solar spectrum. Thus, only small part of the solar energy (~5%) utilized efficiently (Fang, Xing and Zhang, 2017; Khedr et al., 2017). Therefore, it is essential to shift the absorption edge of solar spectrum to the visible region and reduce the recombination of electron-hole (e⁻/h⁺) pairs to enhance the photocatalytic activity of TiO₂. Different modification techniques have been adopted for the effective modification of TiO₂ including non-metal or metal doping, noble metal deposition, semiconductor coupling, carbon-based composite etc. (Hernandez et al., 2017; Shifu et al., 2005). Physical dimension of the materials significantly influence their properties and applications (Michael and Hochella, 2002). Nitrogen doped TiO₂ nanoparticles are proved to be efficient for achieving enhanced photocatalytic performance including photodegradation of organic compounds (Dolat et al., 2015; Devi, Nagaraj and Rajashekhar, 2012) and hydrogen generation from water splitting (Wang et al., 2013; Villa et al., 2012; Naik et al., 2015).

Printing and dyeing wastewater mainly contains complex carcinogenic organic compounds with poor biodegradability (Chen et al., 2017). Photocatalysis could completely degrade organic pollutants into CO₂, H₂O and other mineral acids (Shifu et al., 2007). In addition to that, photocatalytic degradation of industrial effluents is a facile and environmental friendly technology and has developed rapidly in recent years (Yang et al., 2015). In the present

work, Nitrogen doped TiO₂ has been prepared via ultrasonication method and utilised for the effective degradation of methylene blue (MB).

## 2. METHODOLOGY

### 2.1 Materials

Commercial P25 TiO₂ (Evonik, Germany) with BET surface area of 50.68 m²/g was used as photocatalysts. Urea was purchased from Merck. Methylene blue was obtained from LOBAL Chemie. All the reagents were of analytical grade and were used without further purification.

### 2.2. Synthesis of Nitrogen Doped TiO₂ (N/TiO₂)

3 g of TiO₂ nanoparticles were mixed with 6 g of urea in 10 ml of distilled water. The prepared solution was then sonicated for 2 h at 37 KHz. Finally, the sonicated solution was filtered and dried in a hot air oven for 1 h at 100 °C and calcined at 400 °C for ½ h in the muffle furnace with air.

### 2.3. Characterization of Photocatalyst

The absorption spectra N/TiO₂ was recorded with UV-Visible spectrophotometer (Agilent Cary 5000). The morphology and structure of the particles were observed using a field emission scanning electron microscopy (Supra 55 Carl Zeiss Germany). The compositions of the prepared photocatalyst were measured by energy dispersive spectrometry (EDS).

### 2.4. Photocatalytic Activity Evaluation

The photocatalytic activity of prepared N/TiO₂ samples was evaluated by monitoring the photodegradation of methylene blue (MB) in aqueous solution. A 300 W solar lamp was

used as light source and UV-Visible spectrophotometer (Evolution 300 UV-Vis, Thermofisher Scientific) was used for the photocatalytic activity measurements. 0.5 g N/TiO₂ powder was added into a 250 ml of 50 mg/L MB solution. The solution was stirred continuously at 500 rpm by magnetic stirrer in dark for 60 min. for the powder to absorb the MB solution and reach absorption desorption equilibrium. At the end of first 60 min, a sample of 5ml was taken from the suspension by means of syringe filters (0.22 µm) for spectrophotometer measurements. After the first measurement, the solar lamp was turned on and changes in absorbance under simulated solar radiation were measured after every 60 min till 3 hours of continuous irradiation and stirring.

### 3. RESULTS

#### 3.1 Effect of Nitrogen as Co-catalyst

The enhancement of the photocatalytic performance N/TiO₂ was attributed to the enhanced photogenerated electron-hole separation efficiency and the advanced absorption of light. The successful doping of cocatalyst introduces additional energy level in the primary catalyst reducing the band gap of the prepared nanocomposite(Kuvarega, Krause and Mamba, 2015).

#### 3.2 Characteristics of Photocatalyst

Fig. 1 shows the UV–visible absorption spectra of the N/TiO₂ nanoparticles prepared by ultra-sonication method.

The absorption spectra were scanned from 200 to 800 nm to determine the optical properties of the prepared photocatalyst. Band gap of the prepared nitrogen doped TiO₂ semiconductor photocatalyst was calculated to be 2.82 eV.

**Fig. 1. UV–visible absorption spectra of the prepared N/TiO₂ nanoparticles**

Observations by FESEM revealed that all the samples have almost spherical shape with certain agglomeration tendency and size in nano range as shown in Fig.2.

**Fig. 2. FESEM image of the prepared N/TiO₂ nanoparticles**

EDS spectra shown in Fig. 3 confirmed the presence of nitrogen on the surface of TiO₂ nanoparticles. EDS was employed to detect elemental compositions of the prepared photocatalyst.

Fig. 3. EDS spectra of the prepared N/TiO₂ nanoparticles

### 3.3 Photocatalytic Degradation of Methylene Blue (MB) Solution

Methylene Blue (MB) was used as a model dye to estimate the photocatalytic activity of prepared N/TiO₂ sample under simulated solar radiation. The photocatalytic degradation efficiency illustrated in Fig. 4 was calculated by using the following equation.

$$\text{Degradation Efficiency (\%)} = \frac{C_0 - C_t}{C_0} \times 100\% \quad (\text{i})$$

Fig. 4. Photocatalytic degradation efficiency of MB under simulated solar irradiation

The kinetics of MB photodegradation on the photocatalyst surface can be described by the first-order reaction

$$\ln \frac{C_0}{C_t} = kt \quad (\text{ii})$$

Where,  $k$  is the rate constant ( $\text{min}^{-1}$ ),  $C_0$  is the initial concentration of MB and  $C_t$  is the concentration of MB at the irradiation time ( $t$ ). Fig.5 describes the linear relationship of  $\ln(C_0/C_t)$  versus irradiation time ( $t$ ). Rate constant ( $k$ ) was determined for N/TiO₂ photocatalyst from the slope of linear fitting line as shown in Fig. 5. As it can be seen, a good correlation to the first order reaction kinetics ( $r^2 > 0.95$ ) was found.

**Fig.5. Kinetic data for the degradation of aqueous MB under simulated solar irradiation**

#### 4. CONCLUSION

Nitrogen doped TiO₂ prepared via ultra-sonication process exhibits almost spherical morphology with the band gap of 2.82 eV. According to dye degradation experiment results, the reaction followed first order kinetics and prepared N/TiO₂ catalyst shows high photoactivity. The enhanced dye degradation efficiency of N/TiO₂ photocatalyst may be attributed to the enhanced visible light absorption for photoexcitation and charge separation efficiency.

#### ACKNOWLEDGEMENTS

This work was supported by the department of chemical engineering and CRF, Indian Institute of Technology (ISM), Dhanbad.

# A Review on Simulation of Different Process Parameters in Metal Casting and Prediction of Porosity Formation

Mahesh Kavad, S.R. Kulkarni, Rahul Gedekar

Government College of Engineering, Aurangabad, Maharashtra, India

**Abstract:** There are many works has been done on the formation of porosity in the metal casting, but formation mechanism is still not clear. How to decrease the porosity formation cannot be identified and thus it's a main issue in industries. The part rejection in industry up to 40 to 50 % is due to porosity formation in parts either on inner or outer surface. This review paper study many previous works on metal casting porosity formation identified in different parameters, they are depending on porosity formation like mould filling, solidification (melt state change, pore nucleation and pore growth) these are effective parameter during solidification stage. This review paper gives convectional explanation for the prediction of porosity formation using simulation software.

**Keyword:** mechanism, parameter: solidification, moulding filling, heat transfer, feeding flow, simulation, porosity.

## 1. INTRODUCTION

Although many works [Campbell et al., 2015; Vijayaram, 2009] were reported on porosity prediction in ductile material like aluminium, steel and iron but their formation mechanism is still not clear. The porosity is classified into shrinkage porosity and gas porosity but the shrinkage porosity is rare in casting. Most of the casting scrap is assigned as shrinkage porosity. When we observe regions of apparent shrinkage porosity on a radiograph, the oxide bifilms and air bubble arises from the scrambled mess, these are convincing appearance of shrinkage. Generally shrinkage behaviour in the molten metal in furnace occupies considerable more volume than the solid volume of casting. While solidification of molten metal the contraction/shrinkage occurs at three stages as follows

1. First is the liquid contraction also called thermal contraction, the temperature reduces, the volume of the moulded metal reduces almost linearly to compensate falling temperature at this stage liquid metal reduced to compensate for small reduction in volume as show in figure 1, at this stage there is no considerable formation of porosity.

Fig. 1. Different Type of Contraction [Campbell et al., 2015]

2. Second stage is Solidification Contraction. It occurs at freezing point and after at that point reduced temperature. This is the stage where molten metal starts getting solidify thus the density difference among molten metal occurs as show in figure1, so there is more chance of formation of porosity, at the same time solidification contraction started, this contraction causes several problems. If the feeding of molten metal done at solidification stage then the shrinkage porosity formation is greater, the reason behind this is failure of operating of feeding device.
3. The final stage of shrinkage in the solid stage. Almost cooling and solidification is completed and form the predetermined object.

Another type of porosity is gas porosity and affecting parameters are as follows-

1. From air bubble during turbulent pouring.
2. From core blows on chills.
3. From perception of gas in solution in the metal.

## 2. LITERATURE REVIEW

Marek Bruna et al done advance calculation for the prediction of porosity formation for aluminium alloy by advance porosity module included in ProCAST software. In experiment he used thermal analysis to get accurate data about used alloy [marekbruna, 2017].

In this paper the riser size of the aluminium alloys is optimized by using conventional method and AutoCAST simulation software. Work on fluid flow

interdendritic driven on shrinkage and gas porosity help of the chills place on plate at end of chills effect, centre chills effect identify solidification time of casting [Zhao and Liu, 2007].

H. D. Zhao et al based on the model of microstructure formation of SGI casting, a method was proposed to calculate the feeding flow and to predict the macro porosity during solidification of the castings. The simulation results clearly indicated feeding relationship between feeding system and casting body. With the calculation feeding flow, it may be judged and investigated whether an isolated liquid and mushy region expands or contracts [Paine et al., 2002].

The simulation technology has sufficient to prediction of the porosity formation. This paper work on the mould filling simulation of casting process porosity formation. Comparisons of feeding from risers with and without insulating sleeves. The metal in the riser without sleeves shows piping, whereas the metal in the riser containing an insulating sleeve does not show piping. The liquid in the insulating sleeve moves down horizontally and has a large influence on lowering the total level of micro-porosity in the casting [Niels Skat et al., 2013].

Kulkarni et al., 2011, find out the heat transfer during solidification of commercial available Al-4.5% Cu alloy casting CO₂-sand mould was assessed using an inverse analysis technique. The casting/mould interfacial heat flux and the peak heat flux represented the maximum heat transfer from the casting to CO₂-sand mould. The time of occurrence of the peak heat flux transients was nearly five seconds after pouring. During this processing porosity formation can be minimized [Kulkarni, 2011].

### 3. MECHANISM OF POROSITY FORMATION

It seems that porosity formation mechanism has not been cleared so far. The authors propose the following mechanism.

**Mould filling stage-** The mould filling stage should be added, because gas and non-metallic inclusions are entrapped during mould filling and play an important role as nuclei for porosity defects as well as for effective risers [Paine et al., 2002].

**Melt state change -** The melt pressure decreases with solidification because the outer part of casting solidifies first and expands while the inner part cannot expand because of less graphite formation there. The pressure decrease varies with shape and size of castings. The undercooling and mould wall expansion due to melt head can assist this phenomenon. Further, the super saturation of gaseous elements can occur when the concentration of gaseous elements is high. With this pressure decreasing the melt is sucked from risers or other parts where solidification delays and the melt can move. When the outside of risers has

solidified and has no pores, the melt is difficult to move, resulting in more pressure decrease. The effect of inoculation is thought to increase the fluidity of the mushy region.

Although Rivera et al. [30] reported that inoculation was not so effective to nodule grain refining, grains become a bit smaller. If the grains are smaller and, in particular, rounder, the fluidity of the mushy region should be improved, resulting in less pressure decrease and less porosity. The reason why grey iron tends to have much less porosity defects are due to the fact that graphite grows into the melt causing melt pressure increase rather than solidified shell expansion. Further, because grey iron solidifies with skin formation type, the melt is the easily sucked preventing the pressure decrease. In the case of hypoeutectic ductile cast iron, its more connected dendrite network hinders the melt flow, resulting in more porosity defects [Sabau, 2002].

**Pore nucleation-** Pores nucleate, when the pressure in the melt decreases below a critical value, depending on the super saturation and existence of pore nuclei. The most important nuclei maybe the gas bubbles entrapped during mould filling. The authors observed gas entrapment in all castings with X-ray. The gas component can be hydrogen when the mould is green sand mould. However, because we do not have enough data on the gas component in pores, it should be more examined.

The opposite estimation results obtained by the stress analysis by the effect of the gas bubbles entrapped during mould filling compares the mould filling difference of the two castings, the melt in the casting (flows first to the central part and collides in the side cavity, while the flow in the casting fills the cavity smoothly and the melt collides in the riser.

Namely, gas entrapment in the casting is estimated to be less, resulting in fewer nucleuses for pore defects and more bubbles in the riser make the feeding easier from the riser. It is possible that if slag such as Mg₂SiO₄ and 2FeO.SiO₂ generated by the melt treatment is entrapped; CO gas can be generated with the reaction of carbon in the melt [Ohnaka, 2007].

**Pore growth -** The pores grow further with decreasing melt pressure or increasing super saturation of gaseous elements [Campbell, 2005].

**Final state-** The pressure decrease stops and begins to increase when graphite formation rate becomes larger than in the outer part of the casting. The increase in pressure makes the pore smaller but hard to completely eliminate, because it requires very high pressure to resolve the gas pore once formed. Further, the segregation of Al-alloy and Mn and others causes cementite solidification resulting in micro porosity [Sanjuam, 2005].

#### 4. EFFECT OF PARAMETER ON POROSITY FORMATION

The porosity formation in metal casting process is still not identify specific parameter to decreasing porosity formation many stage of the casting process parameter is the effect on porosity formation, this review paper different parameter identifies to the casting process and prediction porosity formation.

**Mould filling-** The Mould filling simulation is prediction of most common problem during filling of molten metal into die these stages atmospheric oxide entrapment occurs largely as a result of turbulence flow, its oxide get pulled into the liquid cavity due to generation of porosity. high turbulence flow is caused due to starting of the flow of basin not fill completely then partial flow of the pour, excessive flow velocities, irregularities in the component geometry, bad pour and gating design, insufficient venting this parameter preventing too difficult to fill without creating turbulence using standard gravity methods and it may mean that the process needs to be changed in order to prevent turbulence [NielsSkat et al., 2010].

To determine the optimal rotational speeds at each stage in the pouring process, in order to maintain an acceptable filling velocity, quite difficult without being able to visualise actually happens to the liquid during filling. Simulation provided information about the liquid flow behaviour during pouring and different rotational speeds to find the optimal condition. Sections that require extra venting can easily be identified and modified to prevent incomplete filling. Approach in finite element modelling (developed by Ch. Piquet and M. Rappaz3) is to use a mesh refinement technique in the mushy zone, which enables the prediction of porosity on a micro scale. In order to simulate porosity and study the effects of gas content, alloying elements, feeding behaviour and pressure on porosity, it isEssential to consider all the physics which govern the formation and growth of pores. The pressure drops in the mushy zone, gas segregation in the liquid and the nucleation and growth of pores needs to be considered to accurately model the formation of porosity [Paine et al., 2002].

**Heat transfer rate-** The heat transfer rate at the at the casting and mould interfere play import role to determining temperature gradient in the solidification of casting, during solidification of the casting controlling factor due to the fact that offering largest resistance to heat transfer flow out into casting into metallic mould is low and the alloy of long freezing range are particular to a type of porosity formation that is observed to generate in layer porosity this condition favourable to formation of porosity indicate to wide range a arising from long freezing time and poor temperature gradients, poor temperature gradient is typical of the alloys

of high thermal conductivity and mould having low rate of heat transfer.

By using simulation software prediction of porosity formation preventing to this problem, previous experimental work on this area its using chills ty to heat transfer rate increasing inner to outer side. Consider the different parameter the simulation made using software procast. Tis software solves the conversation equation using finite element method. This experiment repeats two times first one without chills and second one with six chills compare second result is less porosity formation [Liu et al., 2017].

**Feeding flow-** During the solidification of a casting, the gradual spread and growth of the solid, often in the form of a tangled mass of dendrites, presents increasing difficulties for the passage of feeding liquid. In fact, as the freezing liquid contracts to form the solid, the pressure in the liquid falls, causing an increasing pressure difference between the inside and the outside, generally five types of feeding occurs in casting process like liquid feeding, mass feeding, interdendritic feeding, burst feeding, solid feeding, they assess only the difficulty of interdendritic feeding, they apply best to strong materials such as steels in relatively cold moulds. Here, interdendritic feeding can become impossibly difficult, generating high internal tension in the casting, a condition that the computer would interpret as leading to porosity. However, in conditions in which the solid is softer and can yield plastically, the mould can collapse slightly to give an internally sound casting. Such conditions apply, for instance, in steels cast into hot investment moulds and light alloys in cold moulds where significant solid feeding can occur, causing the criteria function to become inaccurate [Zhao, 2007; Steinbach, 2009]

Criteria functions cannot predict conditions for porosity arising because of the many other mechanisms to produce porosity in castings. These include the major shrinkage pores because of the isolation of major liquid regions, the creation of surface-initiated porosity and the mechanically entrained porosity originating from bubbles of air and mould gases introduced by poor filling systems. Experience shows that in general entrainment defects cause most of the porosity found in casting. Shrinkage porosity is quite rare because, as we have noted previously, founders understand shrinkage and can avoid it. In fact, the ability to avoid shrinkage problems is continuously improving now because of the continuous development of prediction using computer models [Zhao, 2007].

**Solidification contraction -** In general liquids contract on freezing because of the rearrangement of atoms in the liquid structure changes from a rather open 'random close-packed' arrangement to a regular crystalline array of significantly. The densest solids are those that have close-packed face

centred cubic (fcc) and hexagonal close packed (hcp) symmetry. Thus the greatest values for contraction on solidification are seen for these metals. The contractions are in the range of 3.2–7.2%. The solidification shrinkage for the less closely packed body-centred cubic (bcc) lattice is in the range 2–3.2%. Other materials that is less dense in the solid-state contract by even smaller amounts on freezing [Sabau, 2002].

The liquid contraction in casting is the decreasing same volume of molten metal is fill without difficulty but during solid contraction of the metal casting process is very difficult fill solid shrinkage [Campbell, 2015]. The final integrity of a casting is greatly influenced by presence of the porosity, the progressive way to predict presence of porosity is the use of present time modern simulation program. These previous work using thermocouple were placed in different places at the mould for measuring thermal analysis data during experiment and created in proCAST simulation is identify two points is namely coherency Point and rigidity point are also suggested to related with porosity formation during solidification process [Campbell, 2015, Zhao, 2007]. The rigidity point is the solid fraction at which the dendrite structure of solidifying alloy because it mechanically rigid, the rigidity point al-alloys approximate 89 % solid at temperature 561.84°C and 2) The coherency point low solid fraction up to (0-20 %) there is no difficulty feeding of molten metal and coherency point occurs at 17.43 % solid of al-alloys at temperature 607.93°C [marekbruna, 2017].

## 5. POROSITY PREDICTION USING SIMULATION

The computer simulation of casting use different type defects predicted but most common defect on the casting is a porosity due generated porosity formation like mould filling, solidification, feeding is predicted to simulation software. All of the parameter solidification of metal and al-alloys is a complex phenomenon related to these problem made simulation of solidification process is done by running indigenously developed computer software for the metal [marekbruna, 2017].

In the casting process, the program output parameter provided details on time-temperature profile and heat transfer coefficient values they play an important role in the effective design of casting

The aim of simulation of the casting is as follows

1. Predict the pattern of solidification, indicating shrinkage cavities and associated defects may be arises.
2. With simulation the best position selected from various position of casting.

3. Simulation also calculates the change of volume during solidification and weight of the different material in the solid state.
4. Simulation also provides a choice of quality level of casting, for example ignoring of micro porosity [Vijayaram, 2009].

## 6. CONCLUSION

The study of the different type of process parameter and predict porosity formation using casting simulation has become a powerful tool to predict the porosity generation and eliminate them by visualizing mould filling, solidification and cooling rate of the casting and thus it becomes easy to identify the affecting factors of the porosity formation. Decrease in pressure caused by non-uniform solidification and gas bubbles entrapped during mould filling play key role of the formation of porosity. Using simulation by controlling pressure, gases entrapped in casting and reaction of metal helps to minimize of the porosity formation.

⁴Department of Mechanical Engineering, FST, IFHE University, Hyderabad, Telangana, India

**Abstract:** The present study highlights in order to examine the different turning parameters such as spindle speed (N), feed rate (f) and depth of cut (d) on different performance measures during dry turning of AISI D2 Steel using PVD coated carbide tool. Experiments has been conducted according to L9 orthogonal array in order to assess the turning performance characteristics such as material removal rate (MRR) and surface roughness (Ra). Attempt was further made to convert the multi responses into equivalent single response i.e. TOPSIS. In this study, Decision-Makers' (DMs') subjective opinion (in regards of response weight) expressed in linguistic terminology has been transformed into appropriate fuzzy numbers. Fuzzy representation of multiple-judgments have been aggregated and finally defuzzified to obtain crisp weight. Response data thus obtained from machining experiments along with crisp weight of the responses have been utilized in TOPSIS. Finally Taguchi has been implemented in order to determine the optimal parametric combination.

**Keywords:** TOPSIS-based Taguchi approach; AISI D2 steel

## 1. INTRODUCTION

Nowadays, hard turning technology has made tremendous growth and advances in manufacturing industries in order to manufacture of many high precision, high hardness components. AISI D2 steel have been commonly applied in the long run tooling applications, where wear resistance is important, such as blanking or forming dies and thread rolling dies. Hence, it became essential to understand the machinability aspects of these materials.

Kishawy and Elbestawi examined the effect of machining parameters such as cutting speed, feed rate and depth of cut in turning of AISI D2 steel using PCBN tools. They concluded that cutting speeds above 350 m/min, the surface roughness increased with increase in tool wear and this was attributed to material side flow. Konig et al. 1984 noticed that application of PCBN tools in machining of hardened steels improves tool life values as compared to ceramic tools. Aouici et al. (2014) applied RSM and desirability function approach in order to evaluate the optimal process parameter in the turning of AISI D3 steel. Ferreira et al. 2016 done the experimental investigation on the turning of AISI H13 steel with ceramic tools: conventional and wiper. It has been observed that wiper tool reduces the flank wear.

In this paper, TOPSIS coupled with Taguchi philosophy Hwang and Yoon 1981, Lan 2009 has been proposed for optimizing multiple performance characteristics such as material removal rate and surface roughness.

## 2. MATERIAL EXPERIMENTATION

The study analyzed the effect of machining variables such as spindle speed, feed rate and depth of cut in turning of AISI D2 steel. The machining variables are varied into three different levels which is shown in Table I.

**TABLE 1: Domain of Experiment**

Sl. No.	Process parameters	Level (1)	Level (2)	Level (3)
1	Spindle Speed (N)	420	605	787
2	Feed Rate (f)	0.05	0.06	0.07
3	Depth of Cut (d)	2	2.5	3

A series of experiments have been carried out on manually operated lathe (Specification of lathe)) in order to obtain the experimental data. So, proper design of experiments has been essential for experimentation. Therefore, Taguchi has been implemented in order to decide the number of experiments. Here, L9 orthogonal (Table II) array has been selected for conduction of experiments. Cemented carbide too has been used for turning operation. Material removal rate and surface roughness have been evaluated as the machining evaluation characteristics. Following is the equation that has been used to determine the material removal rate.

The surface roughness has been evaluated by a surface roughness tester (Talysurf). Table II shows the experimental results.

**TABLE 2: Design of Experiment (L9 Orthogonal Array) and experimental data**

Sl. No.	N	f	d	MRR [mm3/min]	Ra [ $\mu$ m]
1	257	1.5	0.5	1087.386	3.87
2	257	2	1	803.3234	2.92
3	257	2.5	1.5	637.5	2.46
4	386	1.5	1	1256.97	4.35
5	386	2	1.5	923.789	3.81
6	386	2.5	0.5	708.434	2.16
7	566	1.5	1.5	789.67	3.03
8	566	2	0.5	762.7177	2.66
9	566	2.5	1	1270.528	3.93

### 3. DATA ANALYSIS

For data analysis, data preprocessing i.e. normalization has been carried out (TOPSIS method). The normalized data have been shown in Table III.

**TABLE 3: Calculated normalized values**

Sl. No.	N-MRR)	N-Ra
1	0.384715	0.388243
2	0.284214	0.292938
3	0.225546	0.24679
4	0.444714	0.436398
5	0.326835	0.382224
6	0.250643	0.216694
7	0.279384	0.303974
8	0.269848	0.266855
9	0.44951	0.394263

To determine the priority weight of individual responses, this study has adopted seven linguistic terms i.e. Very High (VH), High (H), Moderate High (MH), Medium (M), Moderate Low (ML), Low (L), Very Low (VL) to collecting expert opinion. Linguistic weight has been transformed into appropriate fuzzy data as shown in Table IV. Subjective expert judgments in relation to response weights have been shown in Table V. Linguistic data translated into fuzzy numbers have been aggregated first (Table VI). The best non-fuzzy performance value (crisp) corresponding to each response has been utilized as crisp weight. The decision matrix has been normalized then and the normalized decision matrix has been shown in Table III. In the next step, the resulting weighted decision matrix has

been constructed (Table VII). Then, the positive-ideal solution (FPIS) and the negative-ideal solution (FNIS) i.e.  $A^+$  and  $A^-$ , respectively, have been determined as shown in Table VIII. The distance for each alternative with respect to positive and negative ideal solution have been computed and shown in Table IX.

**TABLE 4: Linguistic variables for assigning importance weight of each response**

Importance	Abbreviation	Fuzzy weight
Extremely Low	EL	(0, 0, 0.1)
Very Low	VL	(0, 0.1, 0.3)
Low	L	(0.1, 0.3, 0.5)
Medium	M	(0.3, 0.5, 0.7)
High	H	(0.5, 0.7, 0.9)
Very High	VH	(0.7, 0.9, 1)
Extremely High	EH	(0.9, 1, 1)

**TABLE 5: Importance of output responses as given by the Decision-Makers (DMs)**

Output responses	Decision-makers linguistic weight for the responses			
	DM1	DM2	DM3	DM4
MRR	H	H	VH	H
R _a	VH	EH	VH	VH

**TABLE 6: Fuzzy weights and corresponding crisp conversion**

Output responses	Fuzzy weight	Best Non fuzzy Performance value (BNP) Crisp-weight
MRR	(0.55, 0.75, 0.925)	0.725
R _a	(0.75, 0.925, 1)	0.891667

**TABLE 7: Weighted normalized fuzzy decision matrix**

Sl. No.	W-MRR	W-Ra
1	0.278918	0.346184
2	0.206055	0.261203
3	0.163521	0.220055
4	0.322417	0.389121
5	0.236955	0.340817
6	0.181716	0.193219
7	0.202553	0.271043
8	0.19564	0.237945
9	0.325895	0.351551

**TABLE 8: The ideal (best) and negative ideal (worst) solution**

S.No	The ideal (best) $A^+$	The negative ideal (worst) $A^-$
MRR	0.325895	0.163521
Ra	0.193218875	0.389121345

**TABLE 9: Calculated distance measures**

Sl. No.	$S_i^+$	$S_i^-$
1	0.160016	0.123127
2	0.13778	0.134804
3	0.164577	0.169066
4	0.195933	0.158896
5	0.172323	0.087897
6	0.144179	0.196745
7	0.145842	0.124362
8	0.13772	0.15455
9	0.158332	0.166664

After calculating the distance measures, the closeness coefficient has been calculated, and shown in Table X.

**TABLE 10: Closeness coefficients**

Sl. No.	$CC_i$	SNRA	P-SNRA
1	0.434858	-7.23306	-4.36392
2	0.494541	-6.11596	
3	0.506728	-5.90450	
4	0.447810	-6.97812	
5	0.337779	-9.42734	
6	0.577094	-4.77508	
7	0.460253	-6.74007	
8	0.528791	-5.53432	
9	0.512818	-5.80073	

The alternative with the largest relative closeness has been treated as the best choice. The best preference has been determined for the trial no. 12 by Taguchi method. The analysis has been carried out by Minitab software package using Higher-the-Better (HB) criterion. The predicted S/N ratio for the optimal parametric combination ( $N_3 f_3 d_1$ ) (shown in fig. 1) is -4.36392 which is highest among all the computed S/N ratios. Table X, that authenticates the applicability of the proposed TOPSIS based Taguchi method.

**Fig. 1. Evaluation of optimal setting**

#### 4. CONCLUSION

The analysis in this paper exposes that Taguchi's quadratic loss function with Fuzzy TOPSIS to solve the multi response surface roughness characteristics. The taguchi method deals with one dimensional problem and Fuzzy TOPSIS with multi dimensional problem and one performance measurement is required for the multiple responses at each experimental trial. Due to relation between the parameters parametric optimization is difficult to solve but the analysis in this paper demonstrate an optimization approach using orthogonal array and Fuzzy TOPSIS and sound perceptiveness.

# Effect of Cryogenic Treatment on Hardness and Corrosion Resistance of Materials: A Review

Vivek V. Ahire, Sameer M. Sayyad, S. A. Patil.

Government College of Engineering, Aurangabad, Maharashtra, India

**Abstract:** Cryogenic Treatment is used for improving mechanical properties of material. This treatment can be done on components of IC engine, tools, components of Refrigeration and Air conditioning etc. In this paper mainly discuss about Material properties like hardness, strength, fracture toughness, wear resistance, corrosion resistance can be improve by cryogenic treatment as compared to other heat treatment process. Aerospace and tool industries use this treatment to improve the wear resistance, dimensional stability and other mechanical properties.

**Keywords:** cryogenic, deep cryogenic, shallow cryogenic, hardness, wear resistance, liquid nitrogen.

## 1. INTRODUCTION

Cryogenic Treatment is a cooling process carried out after the conventional heat treatment process. Two types of cryogenic process normally used are

- Deep Cryogenic Treatment and
- Shallow Cryogenic Treatment.

In Deep Cryogenic treatment, freezing chamber was maintained around  $-196^{\circ}\text{C}$ . In Shallow cryogenic treatment, freezing chamber was maintained around  $-80^{\circ}\text{C}$ . Treatment of Cryogenic process is carried out in the liquid nitrogen ( $\text{LN}_2$ ) chamber which was well insulated around it. After particular period cryogenic treated component is maintained at room temperature for further cooling.

In Deep Cryogenic Treatment, the high contraction of martensite structure occurs. This contraction forces carbon atoms to diffuse into micro cracks and dislocation sites, which are made during the conventional martensite transformation. Therefore, the fine carbides that improve the wear resistance of steel are formed during the tempering treatment [G Kumar et al., 2016].

Fig. 1. the content of residual austenite [Guo Jia et al., 2014]

## 1.1 Process

Process of cryogenic treatment is as follows:

1. Component is cooled slowly with the help of liquid nitrogen to different temperature limits with different tolerance for particular period.
2. It soaked for that temperature more time due to this, the transformation of retained austenite to martensite occurs.
3. Then slow heating to room temperature [Vengatesh, 2016].

Fig. 2. Standard DCT cycle [Vengatesh, 2016].

## 1.2 Various types of Cryogenic treatment

### 1. Deep cryogenic Treatment

Deep cryogenic treatment is a less expensive process as compared with other, permanent treatment and to partake of changes to whole section of the component, unlike other treatment processes. The treatment is an add-on process to

conventional heat treatment process, in which samples are cooled from room temperature to  $-180^{\circ}\text{C}$  to  $-198^{\circ}\text{C}$  in 3.5 hr at  $1^{\circ}\text{C}/\text{min}$ , soaked at that temperature for 24-36 hrs, slowly heated back to room temperature. [G. Kumar, 2016]

## 2. Shallow Cryogenic Treatment

Shallow Cryogenic Treatment is similar process like deep cryogenic treatment process but only difference is samples are cooled from room temperature to  $-75^{\circ}\text{C}$  to  $-90^{\circ}\text{C}$  in 3.5 hr at  $1^{\circ}\text{C}/\text{min}$ , soaked at that temperature for 24 h, slowly heated back to room temperature. [Idayan, 2014]

Deep Cryogenic Treatment is mostly used than Shallow Cryogenic Treatment because of

- sum conversion of retained austenite in to martensite phase
- Increase in carbide density and their uniform distribution
- Precipitation of fine  $\eta$ -carbides
- The mechanism by which cryogenic treatment can improve the properties of steel is the formation of very small carbides dispersed in the tempered martensite structure. [Vengatesh, 2016]

## 2. LITERATURE SURVEY

G. Hemath Kumar et al., 2016 studied the cryogenic treatment on composite material of Automotive AC system. In this, paper he conclude deep cryogenic treated sample is better than untreated fabricated sample for all types of corrosion which is applicable in refrigeration system. There is an improvement in corrosion resistance of the material because of tight bonding between the grain structures of the material as compared with untreated fabricated composite material.

Guo Jia et al., 2014 studied cryogenic treatment on large rolls of rolling machine. In that he concluded that the most of the residual austenite would be changed into martensite after cryogenic treatment, which contributed to the improved hardness and dimensional stability.

M. Pérez et al., 2014 studied cryogenic treatment on forging die. concluded that cryogenics generate a high internal stress state that activate the carbide nucleation in the first phases of tempering, resulting in a much finer and evenly distributed precipitation which also give rise to a martensite with less carbon, so consequently tougher, at the end of the heat treatment.

A Akhbarizadeh et al., 2009 studied cryogenic treatment on D6 steel tool. It improves the wear rate of D6 compared with the non-cryogenically treated samples and also formation of the micro cracks and the reduction of the lattice distortion.

Rajesh and Hari Singh, 2009 studied the cryogenic treatment on Comparison of optimized settings for cryogenic-treated and normal D-3 steel on WEDM using grey relational theory. In this paper he concluded that the cryogenic treatment the Material Removal Rate decreases, Surface Roughness decreases of the work-piece. Cutting rate is not much affected.

Sanjeev Kumar et al., 2016 studied that Machining performance of cryogenically treated Ti-5Al-2.5Sn titanium alloy in electric discharge machining. The DCT of Ti-5Al-2.5Sn alloy significantly improves the MRR, TWR, SR, and microhardness during EDM in comparison to SCT of the same material which in turn shows improvements when compared to untreated material of the same alloy.

G Venses and R Sri Siva., 2015 studied the Optimisation of Deep Cryogenic Treatment Process on the Wear Resistance of 100Cr6 Bearing Steel. In this paper he explain that The most influencing factor for the improvement of wear resistance using the DCT was identified by the ANOVA as the soaking period.

Hasan et al., 2012 In this paper, effect of Cryogenic Treatment CBN inserts is studied. Cryogenically treated CBN inserts produced less tool wear on titanium than AISI 440 C Martensitic stainless steel and improves wear resistance.

## 3. EFFECT OF CRYOGENIC TREATMENT ON CORROSION RESISTANCE AND HARDNESS PARAMETERS

### 3.1 Corrosion Resistance

The corrosion rate for glass fibre polymer matrix composite material which is used in Automotive AC system untreated is 0.0098315 mm/year and composite deep cryogenic treated is 0.00371 mm/year. For impedance corrosion, the corrosion rate for composite untreated is 0.02715 mm/year and composite deep cryogenic treated is 0.01251 mm/year [G Kumar et al., 2016].

### 3.2 Hardness

Hardness of polymer metal matrix composite is increased from 245.67 HV of untreated component to 279.18 HV of deep cryogenic treated component [G Kumar et al., 2016].

The depth of hardened layer of large rolls used in rolling machine has been thicker and the hardness of the roll has been improved [Guo et al., 2014].

Hardness of AISI 440C Bearing Steel for Raw Material is 20 HRC, Convectional heat treatment process is 57 HRC, Shallow Cryogenic treatment is 59 HRC, and Deep Cryogenic Treatment process is 61HRC.[ Idayan et al., 2014]

Average hardness of tool steel used to make forging dies of Gas quenching and triple tempering component is 43.6 HRC, Gas quenching, cryogenic treatment (-196°C during 12 h) and triple tempering component is 43.6 HRC, Oil quenching and triple tempering component is 43.4 HRC, Oil quenching, cryogenic treatment (-196°C during 12 h) and triple tempering component is 43.1 HRC [M. Pérez et al., 2014].

Hardness of Fe75Ni25 alloy is conventional heat treated process is 174 HV. And is increased in deep cryogenic treatment process up to 336 HV, and 276 HV in Shallow cryogenic treatment process. [Y Kang et al 2011]

#### 4. CONCLUSIONS

The conclusions of this discussion are as follows:

- The Hardness of cryogenic treatment component increased as compared to conventionally heat treated component, this occurs due to the transformation of retained austenite into martensite phase.
- Deep cryogenic treatment is mostly preferred than shallow cryogenic treatment because of its lower deep freezing temperatures which showed more improved properties like, improved wear resistances, increased hardness.

# Experimental Investigation and Analysis for Chatter of Face Milling Tool

Mohit Shrivastava, Nirav Modi, D.H. Pandya

Department of Mechanical Engineering  
L.D.R.P Institute of Technology, Gandhinagar, Gujarat, India

**Abstract:** This paper deals with the experimental investigations of chatter in high speed milling on VMC. In high speed machine tool chatter must be avoided for better machine life, improve surface finish, and increase tool life. The chatter in face milling is reduced by introducing the damper in the cutting tool system also investigation is carried out by introducing the shim attach with insert that provide damping. High speed and hard material applies pressures on the insert seat and shim. The shim acts as a shock absorber for the insert and work piece. The shim protects both insert and tool holder from damage due to high cutting forces. In the present work, the Carbide, Aluminum and Brass shim, material are used to find out their effect on reduction in vibration and improvement in surface finish. Finite Element Analysis (FEA) is done for finding the damping Ratio for different shim material using ANSYS software.

**Keywords:** Chatter, damping ratio, model analysis, ANSYS, VMC.

## 1. INTRODUCTION

In present day's in the manufacturing industries high-speed milling (HSM) plays a crucial role. Some examples include the fabrication of moulds and the aeroplane building industry. The key benefit of high-speed milling is that a large amount of material can be cut in a short time span with relatively small tools due to the high rotational speed of the tool. There is also a demand for increasing the automation in the production. This means that tools and workpieces are changed automatically and that the process is being monitored constantly by various sensors in VMC.

The machining of metals are often accompanied by a violent relative vibration between work piece and tool that is called chatter. There are three different types of mechanical vibrations present as forced vibrations, free vibrations and self-excited vibrations, these are present due to a lack of dynamic stiffness/rigidity of the machine tool

system comprising tool, tool holder, work- piece and machine tool itself.

Successful machining operations depends upon the dynamic relationship between the work piece and cutting tool. Under certain circumstances, the motion of the tool against the work piece can produce a self-exciting system, resulting in large amplitude of vibrations. This vibration or chatter adversely affects the life of the tool, the quality of the cut, and the speed at which operations may be performed. Understanding and properly controlling the interaction of tool/work piece dynamics to control chatter can yield to reduced costs and higher overall productivity.

## 2. LITERATURE REVIEW OF CHATTER IN FACE MILLING TOOL

In order to reduce chatter in face milling tool, some creditable works have provided several literature in below table (see table I).

TABLE 1: Summary of Literature Review

Main criteria	Title of literature	References
High-speedmilling, Regenerative chatter	Prediction of regenerative chatter by modelling and analysis of high-speed milling	R.P.H. Faassen et al. (2003)
Cutting Force Coefficients, HSM, Chatter	Chatter stability prediction in milling using speed-varying cutting force coefficients	N.Grossi et al.(2014)
Chatter prediction, Milling	RCPM—a new method for robust chatter prediction in milling	G. Totis et al.(2009)

Main criteria	Title of literature	References

Aluminum, High-speed Cutting	Design and manufacturing technology of high speed milling cutter for aluminum alloy	Hongbin Chang et al.(2017)

### 3. EXPERIMENTAL SETUP

The experiments were carried out on the CVM 640 (VMC) Milling machine with two face milling tool one is special purpose face milling tool 63 mm dia. 4 inserts cutting tool and second one is 63 mm dia. 5 inserts, work piece Plate of 75*25*300 mm of 2062 mild steel 130 BH work material were used for the experiments. The machining is done using CNMG 120412 (Carbide) insert. The experiments were

conducted at constant feed per tooth 0.15. Three different cutting speed 200m/min, 250m/min, 300m/min are taken, three different depth of cut 0.8mm, 1.0mm, 1.2mm, without shim and with three different shim material Carbide, Brass and Aluminum are taken for experiments. Surface roughness is measured with SJ 210 surface roughness tester (-200  $\mu\text{m}$  to 150 $\mu\text{m}$ ). The experimental setup is shown in Figure 1(a), 1(b), 1(c).

Fig 1(a) Face milling tool Without Shim

Fig 1(b) Face milling tool With shim

Fig 1(c) VMC for milling operation

#### 4. EXPERIMENTAL RESULTS DISCUSSION AND DYNAMIC MOTION BEHAVIOUR

- Experimental results are described in terms of surface roughness for different cutting speed, Depth of cut and Different shim.
- Experimental result as surface roughness for different cutting speed clearly shows that without shim surface

roughness value ranges from 0.78  $\mu\text{m}$  to 2.52  $\mu\text{m}$  and with the brass shim surface roughness value is from 0.84  $\mu\text{m}$  to 1.77  $\mu\text{m}$ . With different shim material Aluminum has surface roughness value from 2.0  $\mu\text{m}$  to 6.92  $\mu\text{m}$ . Carbide has surface roughness value from 2.95  $\mu\text{m}$  to 5.98  $\mu\text{m}$ .

- From this we can clearly state that the Brass is having good surface finish.

Fig 2(a) depth of cut vs surface roughness

Fig 2(b) cutting speed vs surface roughness

TABLE. 2: Experimental Results Table with Shim 4 inserts and No shim with 5 inserts

No. of run	Shim material	Cutting speed	Depth of cut	Surface roughness
1	No shim	250	1.0	1.07
2	No shim	300	1.2	1.08
3	Aluminum	250	1.0	6.05
4	Aluminum	300	1.2	6.65
5	Carbide	250	1.0	4.47
6	Carbide	300	1.2	5.61
7	Brass	250	1.0	0.60
8	Brass	300	1.2	1.06

##### 4.1 Dynamic Motion Behaviour

Different combination of depth of cut, cutting speed, for without shim and with shim material as damper are used with this total 36 experiments based on DOE has been carried out and results of that is obtained in form of motion plots. This plot consists of X direction and Z direction as

cutting force direction for this both operating direction motion analysis has been done with the help of Time domain plots, plot of FFT, plot of point care and orbit plot. Output parameters as surface roughness helps to analyze the motion behavior.

Fig. 3. Brass Shim, Cutting speed 250 m/min and Depth of cut 1.0 mm.

## 5. CONCLUSION

In the present work, a computational model is used for finding out damping ratio and validated with the Experimental study to analyze the chatter in milling operation. The observation of this study can be used to reduce the chatter and improve surface roughness 0.6  $\mu\text{m}$ , 0.8  $\mu\text{m}$  and 1.6  $\mu\text{m}$  where as compared with without shim, brass again gives good surface finish at 250 m/ min (1010 r.p.m ) at depth of cut 1.2 mm and 1.0 mm with surface roughness of 0.6  $\mu\text{m}$  and 1.0  $\mu\text{m}$ . Rather than this result without shim and brass has having same and near approximate surface roughness. Aluminum is not justified for use in operation because of having very high roughness value as 6.9  $\mu\text{m}$ . Conventionally used carbide shim gives poor surface roughness compared to Brass and without shim. From motion behavior again aluminum is not justified for use in operation because of chaotic behavior and conventionally used carbide also gives most of chaotic and multi periodic motion behavior. Motion behavior also justify the concluding results of surface finish. In this

cutting frequency and thrust frequency of brass shim having less value compared with the without shim as well as the motion behavior of brass is having quasi periodic motion (figure 3) and that shows the reduced chatter for most off combination of input parameter compared to without shim.

# Electromagnetic Crimping: Eco-friendly Green Pulse Technology Forming

Jasmin P. Bhimani, Nirav P. Maniar

Department of Mechanical Engineering  
V. V. P. Engineering College, Rajkot, Gujarat, India

---

**Abstract:** Electromagnetic forming is based on Lorentz force. The joining mechanism is creating inference fit by plastic deformation, without any chemical bonding or fasteners. The electromagnetic pulse technology (EMPT) crimping represents a technical and economic alternative to mechanical crimping processes. EMPT provides non-contact processes for joining, welding, forming and cutting of metals by application of strong, short pulsed magnetic fields without using high pressure, high temperature and poisonous gases. This joining method can replace the equivalent of 80 spot welding. The non-contact process that EMPT offers, results in safe, non-hazardous and non-polluted working conditions. Due to these advantages and reduced use of lubricants, EMPT promotes clean room condition and green forming, which is the need of an hour to reduce environment pollution. EMPT is a classical example of integrated approach of advanced eco-friendly manufacturing process, ergonomics and industrial engineering.

**Keywords:** Electromagnetic Pulse Technology, Crimping, Electromagnetic Forming, Lorentz force, EMPT

---

## 1. INTRODUCTION

Ergonomics is the branch of science which deals with providing comfortable, safe, non-hazardous and non-polluted working conditions. Traditional joining processes like welding involve use of high pressure and high temperature. In addition, use of poisonous gases in conventional joining processes result in unsafe, hazardous and polluted working environment which lead to decrease in productivity. Electromagnetic pulse technology crimping technique is an excellent answer to these problems.

EMPT came up in the 1960's and was adopted by many researchers within the following decade. Basically, whenever an electrical current is rapidly imposed within an electrical conductor, it will develop a magnetic field. This change in magnetic field will induce eddy currents in any nearby conductor that generally run in a direction opposite to the primary current like in a transformer. These eddy currents develop their own magnetic field and cause a mutual repulsion between the work piece and actuator. This technique is quite general and is suitable for any workpiece made from a good conductor provided the current pulse is of a sufficiently high frequency. The spatial distribution of pressure can be controlled by the configuration of the actuator and the overall force magnitude is largely controlled by the discharge energy.

The research work covered the fundamentals of the EMPT as well as its applications. Dietz et. al. derived a scheme for calculation of the magnetic pressure acting on the work piece by use of the energy balance equation (Dietz, 1967). Later, the same authors could validate their theoretical considerations by experimental analysis. Within these, they

used Hall-sensors to gain the magnetic flux density distribution data inside a compression coils bore (Dietz, 1969). Bühler and V. Finkenstein manufactured shrink-fit connections between copper tubes and steel rods with the help of the EMPT. However, the bearable force of these connections was quite low (Bühler, 1968). After some years of apparently little scientific interest, research activities in Electromagnetic Pulse Technology (EMPT) again began being increased. However, the field of applications was quite widespread. Beneath further work in fundamentals, like materials behavior, the field of sheet metal forming by EMPT became more and more of interest.

EMPT did not found widespread application in industrial manufacturing processes till now due to low life times of the EMPT system components, especially of the coils used for generation of the magnetic pressure. But it finds its place in modern manufacturing processes due to increased demand of environment friendly world class working conditions. The present volume of this research presents the unique and innovative approach of use of EMPT for joining process.

## 2. WORKING PRINCIPLE OF EMPT

An electrical conductor experiences a force when a current is applied to it in a magnetic field. This force is called Lorentz force after its discoverer. In addition, the current generates a magnetic field itself. Thus, two parallel, current-carrying conductors repel each other, if the currents flow in different directions. If a tube is inserted into an electromagnetic coil, the coil can be seen as one conductor and the tube as the other. An eddy current is induced in the skin of the tube and flows according to Lenz's rule in the

opposite direction to the current in the coil, if an alternating current is applied to the coil as shown in figure 1. Therefore, the tube wall experiences a radial force acting inwards.

EMPT crimping represents a technical and economic alternative to mechanical crimping processes. The non-contact process that EMPT offers, creates a more uniform pressure over the circumference with none of the variation nor tool marks inherent in mechanical processes. Thus the EMPT crimp is more uniform with no radial nor longitudinal misalignment, e.g. when joining metal fittings to rubber hoses as shown in figure 2.

If the coil current changes its direction, the current induced into the tube is also changed. Thus, the coil current and the current induced into the tube remain counter rotating with the direction of the magnetic force is kept constant. The magnetic force compresses the tube radially within microseconds.

However, because of the tube's inertia, the forming process is phase delayed to the pressure build-up. Figure 3 illustrates the forming process at five moments of time.

**Fig. 1. Metallic tube inserted into an electromagnetic coil**

**Fig. 2. Finite element analysis of crimping a tube onto an insert**

**Fig. 3. EMPT crimping of steel fittings onto rubber hoses**

During the rise of the magnetic pressure some microseconds will elapse before first material displacement of the tube is visible. Within this time, internal stresses are built up inside the tube which first must overcome the material's yield strength and the inertial stresses. Subsequently the diameter reduction of the tube takes place. As the process continues, the rate of diameter reduction is significantly increased with a final geometry reached prior to current direction change in the coil. Figure 4 illustrates the correlation between current-time history and displacement-time history for the above given tube compression example. The displacement data are related to the tube's tip point. After  $7 \mu s$  first displacement is identifiable. Only  $15 \mu s$  later, the forming operation is accomplished.

Figure 5 illustrates the correlation between discharge frequency, skin depth and magnetic pressure for an aluminum Al6060 tube of 1mm wall thickness. 80% of the current maximum. The deformation ends, when the current has only slightly exceeded its maximum. In this case, nearly the complete magnetic energy is applied to the moving workpiece. The correlation between discharge frequency and degree of efficiency is caused by 3 fundamentals:

1. The magnetic pressure is dependent on the width of the air gap between coil (or field shaper) and workpiece. When the gap distance increases to more than 1mm, significant magnetic pressure losses are identifiable. Hence, the main portion of magnetic pressure should be applied to the workpiece, before the air gap becomes bigger than 1mm.
2. Maximum magnetic pressure is build up, when the induced current builds up a magnetic field in the same magnitude as the coil's field. i.e. if a single wound coil is used, the current, induced into the workpiece should equal the coil current. For this, the skin depth should be smaller than the work piece wall thickness. Only in this case, inductive coupling losses are minimized.

3. However, there is a frequency dependent damping counteracting the beneficial effects of higher frequencies given in point 1 & 2. According to Winkler, in free tube compression, the radial displacement increases first with increasing frequency. After exceedance of an optimal frequency, the radial displacement decreases again (Winkler, 1973).

**Fig. 4. Current and correlating displacement –time history for a tube compression**

**Fig. 5. Correlation between discharge frequency, skin depth and magnetic pressure for an 1mm wall thickness structural steel tube**

### 3. EXPERIMENTAL SET UP FOR EMPT

As illustrate by Peihui Zhang, (2003) an EMPT systems consist of three major parts: (i) The pulse generator, (ii) a coil and, (iii) a field shaper. The magnetic pressures for forming of metallic materials are in the range of 100 N/mm². To generate these pressures, it is necessary to apply pulsed currents in the range from 100 kA to more than 1000

kA. The energy required has to be stored in a pulse generator, consisting of a capacitor bank, a charging unit and a high current switch. The pulse generator and the coil of the EMPT systems create a resonating oscillating circuit, i.e. the energy

$$E = \frac{1}{2}CU^2$$

which is stored in the capacitors is transferred into the coil with a magnetic energy E and vice versa;

$$E = \frac{1}{2}LI^2$$

Where, C = Circuit's capacitance, U = Charging voltage, L = Inductivity and I = Discharging Current.

Coils and field shapers are used to focus magnetic pressure onto electrically conductive work pieces. The coil consists of one or more electrical windings and is made from a highly conductive material, usually a special copper or aluminum alloy as shown in figure 6. The coil cross-section is usually between 10 and several 100mm² depending on the required currents to transfer.

**Fig. 6. Section of a multiple winding coil**

The field shaper is sectioned with at least one radial slot, and is electrically insulated against the work piece and the coil. The coil length and the field shaper length at its outer diameter are the same, with the gap between coil and field shaper kept as small as possible.

As the electrical pulse is transferred, the coil induces an eddy current in the skin of the field shaper, which flows to the inner surface of the field shaper bore by means of the radial slot. The inner diameter of the field shaper is similar to the outer diameter of the work piece. Glenn S. Daehn

(2006) expressed that the length of the inner bore, however, is usually shorter than that of the coil and thus provides a concentration. This has two effects: firstly, the magnetic field lines are concentrated onto the ridge and, on the other hand, the non-uniform magnetic field of coils with multiple windings is homogenized.

If a field shaper is used, the magnetic pressure that has to be reacted by the coil is smaller than the pressure that acts onto the work piece, thereby significantly increasing the service life of the coil compared to a direct-acting coil, leading to higher efficiency and more favorable costs. The state of the art coils developed by PST products GmbH have been optimised using numerical methods, giving an average coil life time of 2, 000, 000 pulses Schäfer, R. and Pasquale P. (2009)

A variety of work piece diameters and geometries can be processed with a standard coil and the addition of a suitable field shaper with minimal time and effort. A field shaper can be changed within two minutes. A field shaper is not a requirement with many part-specific systems using single purpose coils in service, but can add to plant and part flexibility on the shop floor.

#### 4. WORKING PROCEDURE

The sequence of operation is:

1. The workpiece is positioned in the coil.
2. With the high-power switch initially open, the charging unit charges the capacitors.
3. With charging voltage reached in usually less than 8 seconds, the charging switch is opened and the high-power switch of the coil circuit is closed, releasing the stored energy of the capacitors, providing a sinusoidal alternating current in the providing a sinusoidal circuit of the coil and capacitors.
4. After a few oscillations, the alternating current is damped to zero with the tube shrinking to its final geometry during the first half wave of the alternating current as show in figure 7.

The EMPT systems used in industry generally have a discharging frequency in the range 6 to 30 kHz. EMPT systems developed by PST products GmbH are characterized by very high discharging currents, high discharging frequencies, short cycle times and state of the art process monitoring and control algorithms. The life time of the capacitors is more than 2 million pulses, with scheduled maintenance intervals for the high-power switches approximately every 500, 000 pulses. The discharging currents are between 100 kA and 2000 kA at a voltage of 10 kV to 16 kV, depending on the model as shown in figure 8. The application of electromagnetic crimping for steel tube and for dissimilar materials for

lightweight seat structures of cars and aircraft are shown in figure 9 and 10 respectively.

**Fig. 10. Electromagnetic crimping of dissimilar materials for lightweight seat structures of cars and aircraft**

## 5. CONCLUSION

Electromagnetic pulse technology crimping is a classical example of integrated approach of advanced manufacturing process, ergonomics and industrial engineering. It improves formability i.e. the amount of stretch available without tearing and it suppresses wrinkling. However, there are certain limitations of this technology like non-conductive materials cannot be formed directly, but can be formed using a conductive drive plate. High voltages and currents involved require careful safety considerations. In addition, large sheet metal components cannot readily be formed, due to current limitations on the design of very large coils.

Still EMPT has several advantages in comparison to conventional joining processes. Forming can be combined with joining and assembling with dissimilar components

including glass, plastic, composites and other metals with close tolerances as spring back can be significantly reduced, which leads to increase in productivity. EMPT crimping also reduces tooling costs as single sided dies are sufficient. The foremost advantage is that mechanical contact with the workpiece is not required, this avoids surface contamination and tooling marks. As a result, a surface finish can be applied to the workpiece before forming. It is environmentally clean process as no lubricants are necessary. Compare to conventional forming process, there is no noise in crimping process, which creates better working environment and promotes world class eco friendly working conditions.

# Development of Activated TIG Welding Technology for Duplex Stainless Steel 2205 for Achieving Sustainability

Sagar R.Vaishnani, Jaydip P. Sadhu, Sagar Suthar, Jay J. Vora, Vivek Patel

Department of Mechanical Engineering  
School of Technology, Pandit Deendayal Petroleum University, Gandhinagar, Gujarat, India

---

**Abstract:** Activated Tungsten Inert gas (A-TIG) welding technology is a novel variant of the TIG welding process wherein the penetration capability of the process is enhanced and thus making the process sustainable. In the current study, four different types of fluxes  $\text{SiO}_2$ ,  $\text{ZnO}$ ,  $\text{TiO}_2$  and  $\text{NiO}$  were used for the A-TIG welding process for making bead on plate trials on 6 mm thick plates. Weld surface was observed for extent of spatter and macrostructures were developed for observing the weld bead dimensions. Different aspects of Bead dimensions such as weld depth of penetration, bead width depth to width ratio were measured and analyzed. The results exhibited the full and secure penetration (greater than plate thickness) with  $\text{TiO}_2$  flux. Based on results obtained insights into depth enhancing mechanisms were proposed and role of more than one mechanism was observed with certain fluxes.

**Keywords:** A-TIG, Welding, DSS, sustainability.

---

## 1. INTRODUCTION

Duplex ferritic/austenitic stainless steels are widely used in industries such as chemistry, food, pharmacy, marine etc. due to their high performance characteristics (Badji et al., 2004). Duplex Stainless Steels possess higher strength than austenitic stainless steels, higher toughness than ferritic stainless steels and high resistance to stress corrosion cracking (Chen & Yang, 2002; Jiang, Chen, Huang, & Liu, 2003; Park & Lee, 2001). These desirable properties are due to its two-phase microstructure consisting of approximately equal amounts of austenite and ferrite (Badji et al., 2008; Taban, 2008). These steels possess moderate weldability to almost all conventional welding processes.

Out of all conventional arc welding processes Tungsten Inert Gas (TIG) welding process is one of the most sought process where high quality welds are required (Modenesi, Apolinario, & Pereira, 2000; Naik & Reddy). However, major limitations such as low productivity and relatively shallow penetration particularly in single pass autogenous operation limits the use of this process (Kumar & Sathiya, 2015; Leconte, Paillard, Chapelle, Henrion, & Saindrenan, 2007). A partial answer to this restriction can be provided by applying a thin layer of chemical powder (termed as activating flux) on the surface of the plate before welding and thereby enhancing the weld penetration depth (Dhandha & Badheka, 2015; Vora & Badheka, 2015, 2016a). This technology is termed as Activated TIG (A-TIG) welding process. A-TIG welding has been experimented by researchers in the domain on different steels. An in depth studies was carried out of authors Vora and Badheka (Vora & Badheka, 2015, 2016a, 2016b, 2017) wherein they successfully developed A-TIG technology for the

ferritic/martensitic steels. Their studies on investigation of mechanism and weld morphology proved the fact that the technology can enhance the weld depth penetration drastically. Furthermore authors Naik and Reddy (Naik & Reddy) reported the enhancement in penetration with the A-TIG welding of Duplex stainless steel. Out of several mechanisms proposed for deeper penetration, reversed Marangoni and arc constriction are the major phenomenon held responsible for this enhancement in penetration.

A-TIG welding enables faster welding of the plates by increasing the weld depth of penetration in single pass as compared to other conventional TIG welding process (Naik & Reddy; Ramkumar, Kumar, et al., 2015). Reduction in number of passes, gas consumption, power efficiency and many other features confirms the sustainability of the process. There are limited studies reported in open literature for the A-TIG welding of DSS steels. Thus the aim of current study is to analyze the effect of 4 different single component oxide based fluxes on the weld penetration and mechanisms for the A-TIG welding process.

## 2. METHODOLOGY

The base material Duplex Stainless Steel (2205) used in the present study was procured having chemical composition as shown in Table 1. Four different fluxes such as  $\text{SiO}_2$ ,  $\text{ZnO}$ ,  $\text{TiO}_2$  and  $\text{NiO}$  used in the study were procured in packed and powdered form. The flux available in powdered form is not possible to apply evenly on the weld surface. Thus, the powder is converted to paste form by mixing it with acetone as shown in Fig.1. Acetone has a tendency to vaporize quickly leaving the evenly distributed oxide flux on the surface. Base material plate of 6 mm thick was cut into

strips of 100 × 25 (mm) for bead on plate trials and flux paste was applied on 10 mm width at the center of strip throughout the length as shown in Fig. 1 with a paint brush. Flux thickness was taken approximately as 0.15 mm. In order to ensure this, the quantity of flux was calculated as shown in Table 2 and entire amount of flux was applied over the desired area. For having a uniform amount of flux

constituents over entire length of strip, the brush was moved in both forward and reverse direction over the desired area until entire flux paste was consumed. In order to measure the peak welding temperatures, a contact type “K” type thermocouple was fixed at the center of the plate by drilling a hole of approx. 2 mm diameter and 3 mm depth during the welding trials.

**TABLE 1: Chemical composition of base material DSS 2205**

Element	%C	%Si	%Mn	%P	%S	%Cr	%Ni	%Mo	%N	%W
wt. %	0.02	0.299	1.657	0.023	0.005	22.946	5.441	3.068	0.158	0.03

**TABLE 2: Flux weight and Peak welding temperature**

Flux	Density (g/cm ³ )	Weight of Flux (gm)	Peak Temperature (°C)	Voltage (V)
No Flux	-	-	656	13.5
SiO ₂	2.65	0.397	723	13.5
ZnO	5.61	0.841	763	13
TiO ₂	4.23	0.634	1050	13.5
NiO	6.67	1.001	1010	13.5

**Fig. 1. Preparation and application of flux paste.**

Extensive welding trials were conducted using the welding parameters as welding current 160 A and travel speed 120 mm/min. The arc was moved along the centre line of the welds and all the welding parameters were controlled, however arc voltage which is not normally a control parameter was measured. In order to compare the effect of oxide fluxes, samples were welded with same operating conditions by applying four oxide fluxes individually as well as TIG welding without flux.

After welding, samples were taken from the centre of the welded plate and subjected to mechanical grinding, polishing followed by etching using Adler’s Reagent to produce a bright surface. A Digital Camera/Stereo Microscope was used to observe all the samples.

### 3. RESULTS AND DISCUSSION

#### 3.1 Effect of Oxide Fluxes on Weld Surface

The weld surfaces of plates prepared using TIG and A-TIG welding process using different fluxes are as shown in Table 3. It can be observed that a spatter free surface was attained using TIG welding whereas varied amount of spatter was obtained at the periphery of the A-TIG welded bead (Vora & Badheka, 2015). The extent of spatter found on the front surface followed the descending order using fluxes NiO > SiO₂ > TiO₂ > ZnO. This was attributed to the slag layer formed due to the flux layer applied before welding.

As observed on the back side, full & secure penetration (> than plate thickness) was obtained for A-TIG welded sample using fluxes NiO and TiO₂. On the other hand, with the use of fluxes ZnO and SiO₂ there are no sign of any full depth penetration. Notably TiO₂ gives full length secure more than plate thickness penetration. While NiO flux is not able to give throughout length penetration. The reason for the same may be absence of stable and thorough depth enhancing mechanism along the length.

#### 3.2 Effect on Weld Bead Dimensions

The weld bead dimensions are as shown in Fig. 2. It can be seen from the table that flux TiO₂ gave penetration of 6.82 in a 6 mm plate. While though NiO imparted full depth penetration but the penetration profile was not continuous through the length. An important consideration which can be observed was that, fluxes ZnO, SiO₂ tends to increase the penetration as compared to normal TIG welding, however full and secure penetration was not obtained. Furthermore, it can also be observed that the Depth to

Width (D/W) ratios for all the fluxes are found to be higher compared to TIG welding without flux (Fig. 3). This, indicates, the presence of reverse Marangoni flow which is one of the main activation mechanism. In reversed Marangoni flow the direction of fluid flow (molten metal in present case) during welding is radially inwards giving a deeper and narrower bead (Dhandha & Badheka, 2015; Nayee & Badheka, 2014; Ramkumar, Bajpai, et al., 2015; Vora & Badheka, 2015). However, The drastic penetration increase in case of NiO and TiO₂ hinted towards the existence of another depth enhancing mechanism which responsible for deeper penetration.

### 3.3 Effect on Peak Welding Temperatures

Table 2 also shows the Peak temperature values attained

during TIG and A-TIG welding. It can be observed that the peak temperatures achieved with the use of fluxes TiO₂ and NiO are much higher compared to TIG welding. This may be due to the presence of arc constriction mechanism (Berthier, Paillard, Carin, Pellerin, & Valensi, 2012; Shyu, Huang, Tseng, & Chou, 2008; Tathgir, Bhattacharya, & Bera, 2015; Vora & Badheka, 2015, 2016b). Arc constriction mechanism tends to focus the arc energy towards the centre by constricting the arc shape. The total arc energy which was same in all cases (all fluxes) was concentrated at the centre which increased the peak temperatures even though the welding conditions and parameters were same. Relatively similar peak temperature values with fluxes SiO₂ and ZnO indicated a complete absence of this phenomenon. This may be the reason for limited penetration increase with these two fluxes.

**TABLE 3: Surface appearance of welded plates and Macrostructure**

	Surface Appearance Of Welded Plates		Macrostructure
TIG Welding	FRONT		
	BACK		
A-TIG Welding with SiO ₂ Flux	FRONT		
	BACK		
A-TIG Welding with ZnO Flux	FRONT		
	BACK		
A-TIG Welding with TiO ₂ Flux	FRONT		

Fig. 2. Weld Bead Dimensions

Fig. 3. D/W ratio for different fluxes

#### 4. CONCLUSION

Based on the study conducted, following important conclusions can be proposed.

- Full and secure penetration was obtained with the use of fluxes  $\text{TiO}_2$  and  $\text{NiO}$  however with the flux  $\text{NiO}$  penetration profile was not continuous through the length
- Fluxes Study shows the presence of reverse Marangoni flow which is one of the main activation mechanism for increased penetration compared to conventional TIG Increase in the D/W ratio with the use of oxide fluxes proved the presence of reversed Marangoni effect during A-TIG welding.
- Higher peak welding temperatures during the A-TIG welding with fluxes  $\text{TiO}_2$  and  $\text{NiO}$  indicated the presence of arc constriction mechanism which was completely absent with other fluxes.

Selected process parameters along with the suggested fluxes can be further tried for full size butt welding of 6 mm thick DSS steel plates.

# Design and Structural Analysis of Missile Nozzle

A. Chandrashekhara, Palla Teja

Department of Mechanical Engineering  
Faculty of Science and Technology, IFHE University, Hyderabad, Telangana, India

---

**Abstract:** Nozzle is the component of a missile, rocket or air breathing engine that produces thrust. Converting the pressure of the hot chamber gases into kinetic energy and directing that energy along the nozzle axis. The nozzle considered for analysis in this project work is designed for short range missile and is made of maraging steel 250 alloy. In this work stress analysis of this nozzle under the different static test pressures are considered. Nozzle is modeled in SOLIDWORKS and analysis is carried out in ANSYS 14.0. Finite Element Analysis is carried out to find the stresses, thermal flux and displacement in nozzle components. Finally, from the results it is concluded that the structure is safe and has adequate margin of safety in components of nozzle assembly.

**Keywords:** SOLIDWORKS, ANSYS, Nozzle, Missile.

---

## 1. INTRODUCTION

Nozzle is the component of a missile, rocket or air-breathing engine that produces thrust. Converting the pressure energy of the hot chamber gases into kinetic energy and directing that energy along the nozzle axis.

The propellant is composed of a fuel, typically liquid hydrogen (H₂), and an oxidizer, typically liquid oxygen (O₂). The propellant is pumped into a combustion chamber at some rate ( $\dot{m}$ ) where the fuel and oxidizer are mixed and burned. The exhaust gases from this process are pushed into the throat region of the nozzle. Since the throat is of less cross-sectional area than the rest of the engine, the gases are compressed to a high pressure. The nozzle itself gradually increases in cross-sectional area allowing the gases to expand. As the gases do so, they push against the walls of the nozzle creating thrust. Mathematically, the ultimate purpose of the nozzle is to expand the gases as efficiently as possible so as to maximize the exit velocity ( $V_{exit}$ ). This process will maximize the thrust ( $F$ ) produce by the system since the two are directly related by the equation

Where  $F$ =Thrust force

$\dot{M}$ =Mass flow rate,

$V$ =Exit exhaust gas velocity at nozzle exit,

$p$ = Exit pressure of the exhaust gases at the nozzle exit

$P$  = Ambient pressure of the atmosphere

$A$ = Exit cross-sectional area of the nozzle exit.

## 2. EXPANSION AREA RATIO

In theory, the only important parameter in missile nozzle design is the expansion area ratio ( $e$ ), or the ratio of exit area ( $A_{exit}$ ) to throat area ( $A_{Throat}$ ). Fixing all other variables (primarily the chamber pressure), there exists only one such ratio that optimizes overall system performance for a given altitude (or ambient pressure). However, a

missile typically does not travel at only one altitude. Thus, an engineer must be aware of the trajectory over which a missile is to travel so that an expansion ratio that maximizes performance over a range of ambient pressure can be selected. Nevertheless, other factors must also be considered that tend to alter the design from this expansion ratio-based optimum. Some of the issues designers must deal with area nozzle weight, length, manufacturability, cooling (heat transfer), and aerodynamic characteristics.

## 3. MATERIAL

The nozzle is critical component of the missile. Material used to manufacture nozzle should possess high strength, high temperature resistant, good machinability. The nozzle components are made of 18 Ni maraging steel 250 (ASTM A579 Code 72). This material used in annealed condition to acquire high strength, good machinability and resist the high temperature.

## 4. DESIGN CONSIDERATION

Nozzle consists of three parts they are:

**Nozzle End Dish:** - Nozzle end dish is fixed to combustion chamber. So the left end of the nozzle end dish is constrained i.e., translation and rotational movements are arrested ( $u_x=u_y=u_z=0$ ).

**Nozzle Neck:** - Nozzle neck is fixed to nozzle end dish. Hot gases from hot chamber flows to nozzle neck through the end dish. The diameter of nozzle decreases from end dish to neck.

**Nozzle Cone:** - Nozzle cone left end is fixed to the nozzle neck and the other end is free. From nozzle cone high pressure gases extruded to outside by this pressure only missile can move with high velocity.

## 5. PROBLEM SPECIFICATION

Nozzle is attached to combustion chamber and it exerts high pressures and temperature. It consists of three components end dish, neck and cone. The end dish is subjected to both radial pressure and thrust. Neck and cone subjected to radial pressure. The components are analysed for strength considering material properties at elevated temperature. Also temperature fluxes are calculated for the nozzle.

## 6. TYPES OF NOZZLES

**Conical nozzle:** Most military jet air craft employ the simple conical nozzle with adjustable conical angle as their propulsive device. In this conical nozzle external supersonic expansion occurs.

**Bell shaped nozzle:** In this nozzles exhaust gases are forced into a converging throat region of low area before expand in bell shaped nozzle. In this nozzle expansion occurs internally.

**Convergent-divergent nozzle:** This nozzle has convergent section followed by a divergent section so called as convergent divergent nozzle. From inlet heat gases to the throat (minimum area) and then decelerates. As pressure is lowered the flow eventually chokes.

## 7. DEVELOPMENTS IN MISSILE NOZZLE

Through the concept of the nozzle has been around for many years, little actual flight or test experience has been available until recently.

### 7.1. Early Development

The first serious studies of nozzles were performed in Germany in conjunction with the development of the turbojet engine. Engines like those used on the Messer Schmitt me 262, utilized a plug center body to vary the throat area for better performance. Jeffry J. Berton scientist of NASA said that the United States air force. And missile dyne together spent over \$500 million on the development of engines during the 1950s, 1960s, and 1970s.

The development effort conducted by the NASA Lewis Research Center (now known as NASA Glenn) in Cleveland, oh, and by Missile dyne's Nevada test Facility, tested aero spike engines ranging in size from subscale cold-flow models to a full-scale 250, 000lb thrust engine. These tests included 73 ground tests of full-sized engines totaling over 4000 seconds of operation. Similar work was underway in West Germany from 1965 to the early 1970s in support of a heavy lift launch vehicle called Neptune. The propulsion arrangement for this concept consisted of a "toroidal plug nozzle" that behaved much like an aero spike with primary and secondary flows.

## 8. NOZZLE MATERIAL AND ITS PROPERTIES

High Temperature Materials and Their Requirement Recent developments in nuclear power, jet aircrafts, ballistic missiles and rocketry have increased the demand for materials that have good corrosion resistance, strength characteristics and particularly, creep resistance at high temperatures. High temperature use of materials can give rise to several problems such as:

1. Accelerated oxidation and/or corrosion.
2. Creep.
3. Grain boundary other weakening.
4. Allotropic and other phase changes.
5. Modification of conventional properties.

Therefore, the material for high temperature use must be such that it can withstand these difficulties and perform its functions satisfactory during service. The nozzle components are made of 18 Ni maraging steel 250 (ASTM A579 Code 72). This material used in annealed condition to acquire high strength, good machinability and resist the high temperature. The composition used for this material is given in table.

## 9. COMPOSITIONS

TABLE 1: Chemical composition of maraging alloy 250

Chemical Elements	Min	Max
Nickel	17.0	19.0
Molybdenum	4.6	5.1
Cobalt	7.0	8.5
Carbon	-	0.03
Aluminum	0.05	0.15
Phosphorus	-	0.01
Sulfur	-	0.01
Silicon	-	0.10
Titanium	0.3	0.5
Manganese	-	0.01
Iron	68.0	-

In order to withstand high pressure and temperatures, its strength is acquired by the composition of these materials like Carbon, Nickel, Sulphur, Manganese, Titanium, Silicon and Molybdenum etc.

### 9.1. Nickel

It increases the strength and toughness of the steel. Nickel contributes great strength and hardness with high elastic limit, good ductility and good resistance to corrosion. An alloy containing 25% of nickel possesses maximum toughness and offers greater resistance to rusting, to rust in corrosion and burning high temperature. It has zero coefficient of expansion.

### 9.2. Manganese

It improves the strength of the steel in both the hot rolled and heat treated condition.

### 9.3. Silicon

It behaves like Nickel it has high elastic limit as compared to ordinary carbon steel.

### 9.4. Cobalt

It gives red hardness by retention of hard carbides at high temperatures it tends to the decarburize steel during heat-treatment. It increases hardness and strength and also residual magnetism and coercive magnetic force in steel for magnets.

### 9.5. Molybdenum

It posses extra tensile strength and is used for air-plane fuselage and automobile parts. It can replace in high speed steel.

## 10. GENERAL CHARACTERISTICS

This composition has following characteristics

1. Good machinability.
2. Good surface finish.
3. High strength.
4. Excellent corrosive resistance.

## 11. MODELLING OF NOZZLE

### 11.1 Analysis of Nozzle

Analysis of the Nozzle is carried over in the following steps:

**Building the Model:** Where the geometry of nozzle is specified and model is created in SOLIDWORKS.

**Applying the Load:** This is carried out in ANSYS14.0. Meshed model is imported to ansys and pressures are applied.

Viewing the Results: This is also carried out in ansys. In this we can view stresses and deformations.

**GEOMETRIC MODELLING:** Modelling has been carried over in SOLIDWORKS software is very easy modelling critical components. SOLIDWORKS is very user friendly and parametric.

## 12. PRESSURE LOADS

COMPONENTS	PRESSURE LOADS
NOZZLE END	10
NOZZLE NECK	5
CONE	2

Pressure loads are used for structural analysis.

**ALL LOAD ARE IN MPA**

## 13. RESULTS

**RESULTANT DISPLACEMENT**

**STRESS**

### 12.1 Resultant displacement and stress according to load

DISPLACEMENT:-4.17e5

STRESS:-181.05

REMARKS:-safe

## 14. CONCLUSION

The Nozzle is analyzed for different inertia load cases in addition to test pressure. A global final element analysis (FEA) (static analysis only) is carried out to arrive at the stresses and deformations in critical components. Finally from the results obtained, it is concluded that all the stresses induced are well within the allowable limits and the structure is safe.

# Process Parameters Optimization of Friction Stir Welded Butt Joint: A Review

S. P. Wanare¹, V. D. Kalyankar²

¹Department of Mechanical Engineering

G. H. Raisoni College of Engineering and Management, Amravati, Maharashtra, India.

²Department of Mechanical Engineering, Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

**Abstract:** Friction stir welding plays vital role in industrial revolution for joining similar and dissimilar metals. This review paper mainly concentrates on various advanced optimization techniques used by previous researchers for finding out the optimum values of process parameters with their effects. In this paper, various methodologies and optimization aspects are thoroughly overviewed and critical observations are noted down. The graphical representation shows the most influencing process parameters and best-suited optimization technique is suggested which may become ready information for the forthcoming researchers to establish their line of action. This review paper is also helpful for finding out the effect of various process parameters such as tool rotational speed, welding speed, tool pin profile, tool pin diameter, tool shoulder diameter, the ratio of tool shoulder diameter to tool pin diameter, tool tilt angle, tool plunge depth, axial force, etc.

**Keywords:** Friction stir welding, Optimization, Tool rotational speed, Welding speed, Axial force, Tensile strength

## 1. INTRODUCTION

The researchers working in aerospace, marine, automotive and rail industries are more concerned for the reduction in energy consumption by using several lighter alloys. Aluminum, copper, magnesium and nickel based alloys can be extensively used due to their exclusive properties such as low density, high strength to weight ratio, high formability, good corrosion resistance, etc. Joining of these alloys by using conventional fusion welding processes is a tedious job and results in various welding defects such as porosity, distortion, solidification cracking, etc.

The exclusive feature of FSW is its ability to join metals below their melting temperature, hence reduces welding defects which occurs due to uneven heat distribution. FSW finds large application in aluminum based industries, however recently it is also used for joining copper, titanium, magnesium, nickel based alloys and plastics. FSW is becoming more popular as it can join similar as well as dissimilar metals for making weld joints from 1 mm thickness to 80 mm thickness. FSW is used for fabricating various welding joints such as butt weld, spot weld, lap weld, T-joint, continuous drive friction welding for joining two cylindrical rods, tube to tube plate weld joint, etc.

## 2. REVIEW OF PROCESS PARAMETERS OPTIMIZATION OF FSW FOR BUTT JOINT

Friction stir welding for obtaining butt weld joint (Fig.1) uses non-consumable tool which rotates at high-speed and when comes in contact with the metal to be joined, it produces heat due to friction which in turn allows the material to be softened. Due to the rotation of tool, this

softened material is forced to flow from front to the back of the tool pin where it cools and solidifies, which produces weld joint. Since the welding takes place below melting temperature, it significantly reduces distortion and other welding defects. The FSW process involves various process parameters such as tool rotational speed (TRS), welding speed (WS), tool pin profile (TPP), tool pin diameter (TPD), tool shoulder diameter (TSD), ratio of tool shoulder diameter to tool pin diameter (D/d), axial force (AF), tool pin length (TPL), tool geometry (TG), tool tilt angle (TTA), tool pin rotational speed (TPRS) assisted shoulder rotational speed (ASRS), plate thickness (PT), etc. The output responses considered are tensile strength (TS), yield strength (YS), hardness (H), elongation (E), ultimate tensile strength (UTS), etc.

Fig. 1. Schematics of the friction stir process for butt joint (Mishra and Ma, 2005)

From the literature review, it is observed that most of the research work is carried out on FSW butt joint configuration since its wide application in industries. In this article, an attempt has been made to overview most of the

**Table I :** Summary of FSW process parameters optimization review

Author (s), Year	Input variable (s)	Objective(s)	Material	Machine	Tool specification(s)	Optimization technique (s)	Conclusion	Critical observation(s)
Jayaraman et al., 2009	TRS, WS and AF	TS	A319 (175 mm X 75 mm X 6 mm)	FSW machine	High carbon steel tool	Taguchi method	TRS is found to be most influencing parameter	All parameters are having significant effect on TS
Tansel et al., 2010	TRS and WS	TS, YS, E, H of weld metal, H of HAZ	AL plates (Al 1080) (5×50×150 mm)	FSW machine	High speed steel tool of 20mm diameter and 4mm plunge depth	GONNS	GONNS is found to be suitable for optimization of process parameters	The ANN-GA combination is recommended for other optimization problems
Biton et al., 2010	TRS and WS	UTS and YS	3.2 mm thick rolled sheet of AA 2198 T3	Five axes DMG CNC machine	Cr-Mo steel tool of TSD = 24 mm, TPD = 4 mm, PD = 3mm and TTA = 2°	The desirability function algorithm	UTS is dependent on rotational speed of tool and YS is strongly dependent on welding	The weld joints performed in cold condition have good mechanical properties
Aydin et al., 2010	TRS, WS and TSD	TS and E	AA1050-H22 (360 mm × 200 mm × 4 mm)	Vertical milling machine	High speed steel tool (HSS)	Grey relation analysis and Taguchi approach	Rotating speed of tool has highest contribution of 65.61 % on output response.	Grey based Taguchi method can be effectively used for solving multi-objective optimization
Koilraj et al., 2012	TRS, WS, TG and D/d	TS	AA2219 and AA5083 (150mm × 65mm × 6mm)	FSW machine	H13 grade tool steel	Taguchi method	Butt joint Efficiency found to be 90%. The D/d ratio is the most influencing parameter	Better mechanical properties are obtained if stronger metal is placed on advancing side
Dinaharan and Murugan, 2012	TRS, WS and AF	UTS	AA6061/ZrB2 plates (100 mm × 50 mm × 6 mm)	FSW machine	high carbon high chromium steel tool	Generalized reduced gradient method	The increase in TRS, WS and AF to a certain limit increases UTS and then decreases.	Generalized reduced gradient method is attempted by very less researchers
Bozkurt, 2012	TRS, WS and TTA	UTS	HDPE sheets (50mm X 130mm X 4mm)	FSW adapted milling machine	SAE 1050 Steel tool 40 HRC having TPD = 6mm and shoulder diameter = 18mm	Taguchi method	The most important factor is TRS having 73.85 % contribution	It is observed that HDPE sheets can be successfully welded by FSW
Vijayan, Raju and Rao, 2012	TRS, WS and AF	TS	AA5083 (300mm × 150mm × 5mm)	FSW machine	M2 steel tool with TSD = 15mm and TPD = 5mm	Grey relation analysis and Taguchi approach	The rotational speed of the tool is found to be the most significant factor	It was observed that the input power increases significantly with increase in the axial force

Table I : (Continued..)

Author(s), Year	Input variable (s)	Objective(s)	Material	Machine	Tool specification (s)	Optimization technique(s)	Conclusion	Critical observation(s)
Babajanzade et al., 2013	AF, TRS, WS, and TG	YS, H and TS	AA7075 (200 mm x 100 mm x 6mm)	CNC milling machine	High speed steel tool	ANFIS	ANFIS System has good competency for optimizing process parameters	Less number of researchers used ANFIS system for optimization
Periyasamy et al., 2013	TRS, WS and AF	UTS, notch TS and weld nugget hardness	AA6061 (150 mm x 100 mm x 6 mm)	FSW machine	high speed steel tool	RSM	The TRS is found to be most influencing parameter followed by WS and AF	TRS is mainly responsible for increasing the temperature at weld joint
Al-Jarrah et al., 2013	WS, TSD, TRS and PT	YS and H	Aluminum alloy having 4.2 % Mg and 0.42 wt % Si	Milling machine	High carbon steel tool	RSM	The results obtained were matched with welding appearance quality and experimental results	Optimum range of input variables can be obtained by conducting more number of trail experiments
Bilgin, Meran and Canyon, 2014	TRS, WS, AF and TTA	TS	AISI 430 (3 mm x 100 mm x 200 mm)	Vertical milling machine	A cemented carbide equilateral triangle tip tool	Genetic algorithm	The optimum values are TRS = 1120 rpm, WS = 125 mm/min, CTF = 4.5 KN and TTA = 0°	Quality of joint is quite poor having lower TRS with higher WS and having higher TRS with lower WS
Shojaeefard, Akbari and Asad, 2014	TRS and WS	Peak temperature, HAZ width	AA5083 Alloy 6mm thickness	CNC milling machine	High speed steel tool	A Thermo-mechanically coupled, 3D FEM	Welding force decreases with increase in TRS and decrease in WS. This may lead to increase in tool life	The training algorithm of back-Propagation is sufficient for Predicting peak temperature, HAZ zone width and welding
Ahmadi, Arab and Ghasemi, 2014	WS, TRS and TTA	Tensile shear strength	Polypropylene sheets with 20 % carbon Fiber	CNC milling machine	HSS tool with TSD = 12mm, TPD = 4mm	Taguchi method	The percentage contribution of process parameters found as follows WWS = 79.06 %, TRS = 12.29 % and TTA = 5.41 %	FSW can be successfully implemented to polypropylene composites and it was attempted by very few
Elanchezhia et al., 2014	TRS, WS and AF	Impact strength and TS	AA6061 and AA8011(160 mm x 50mm)	CNC milling machine	HSS tool	Taguchi method	ANOVA results show that the contribution of TRS is higher i.e. 35.79 % for impact strength and contribution of AF is higher i.e. 64 % for TS	In this paper impact tests were conducted on charpy machine according to specifications of ASTM-E23.
Loffi and Nourouzi, 2014	TRS, WS and TSD	TS and micro hardness	AA7075-T6 (3x 150 mm x 100 mm)	FSW machine	H13 hot work tool steel	RSM	With increase in TRS and WS the TS and micro hardness increases and then decreases steadily	Preheating system gives improved mechanical properties and defect free joint

Table I : (Continued..)

Author(s), Year	Input variable(s)	Objective (s)	Material	Machine	Tool specification(s)	Optimization techniques	Conclusion	Critical observation(s)
Dhancholia, Sharma and Vyas, 2014	TRS and WS	TS, YS, H and impact strength	AA6061 and AA7039	CNC milling machine	HSS tool of TSD= 16mm and probe length = 4.7mm	RSM	TRS and WS found as most influencing parameters	Multiple response problems can be easily solved using desirability method
Kumar and Kumar, 2014	TRS, TTA and TG	TS and % E	AA6061 and AA6082 ( 100 mm x 35mm x 7.5mm)	CNC milling machine	HSS tool TSD = 16 mm and TPD = 6mm	Taguchi based grey relation analysis	The TRS found to be the most influencing process parameter having 96.24 % of contribution	It was observed that the overall cost of experimentation was minimized because it provides optimum solution with minimum trials
Rambabu et al., 2015	TRS, WS, TPP and AF	Corrosion resistance	AA2219-T87 ( 240 mm x 160 mm x 7 mm)	FSW machine	HSS tool	SA algorithm	The most influencing process parameter is found to be TG and hexagonal tool pin profile	A computer program using MATLAB for the algorithm was developed to optimize the process variables
Li, 2015	WS, TRS, ASRS	TS	AA2219 (300 mm x 80mm x 5mm )	FSW machine	HSS tool	RSM	Improvement of 5.2 % maximum TS of reverse dual rotation FSW was observed	The direction of tool pin and assisted shoulder are reversed which increases TS of FSW joint
Sahu and Pal, 2015	WS, TRS, TSD and TPL	UTS, YS % E, H, compress ive	AM20 Mg alloy ( 100 x 100 x 4 mm )	FSW machine	H13 tool steel TSD= 16-24 mm, TPD= 6 mm and PD 3.5 mm	Taguchi Grey relational analysis	The most influencing parameter is shoulder diameter for Case I and welding speed for case II	Grey relational analysis with Taguchi technique shows better mechanical properties for multi- objective optimization of
Vijayan and Rao, 2016	TRS, WS, AF and TPP	UTS and tensile E	AA 6061 & AA 2024 (300mm x 150 mm x 6.25mm )	CNC vertical milling machine	H13 Hot work steel tool	ANFIS	The ANFIS model using "gbelimf" is accurate and can be used to improve TS	It shows that ANFIS models are capable of generating better predictions of tensile properties compared to RSM
Alkayem, Parida and Pal, 2016	TRS, WS, TG, D/d and TPL	UTS, YS, % E, bending angle and H	Al alloy (wt %) Cu- 0.05, Si-0.2, Fe-0.1, Al-balance and 200mm x 100mm x 6mm size	CNC milling machine	Stainless steel (SS-310)	GA, differential evolution (DE), PSO	The real GA, DE and PSO are able to find weld characteristics which are better than binary GA	From the aforesaid case study, it is observed that PSO is more suitable for optimization of FSW Process
Liu et al., 2017	TPRS and ASRS	Temperat ure variation	Aluminum 5A06 alloy	FSW machine	HSS tool	Finite element analysis	It was concluded that the successful welding can be achieved	The thickness of plates to be welded was considered as 80mm which is very large

previous research work which uses various advanced optimization techniques for the process parameter optimization of FSW for butt joint configuration. It was observed that, Taguchi method and Response surface methodology is mostly used to get optimum values of process parameters. Experimental welding Investigations were carried out considering different Input variables and their effects on output responses. In some cases various advanced optimization techniques were used such as Simulated annealing (SA), Particle swarm optimization (PSO), Response surface methodology (RSM), Genetically optimized neural network system (GONNS), Adoptive neuro-fuzzy interference system (ANFIS), etc. Table 1 shows summary of reviewed research papers for optimization of FSW process parameters.

### 3. CRITICAL OBSERVATIONS FROM LITERATURE REVIEW

From the literature review, the graph is plotted (Fig. 2) showing the frequency of process parameters used by the previous researchers. It is observed that the most influencing process parameters are tool rotational speed, welding speed and axial force.

- ii) The effects of process parameters observed from literature review are
  - a) The TS of weld joint increases with increase in TRS up to certain value and decreases if TRS further increases.
  - b) TRS is directly proportional to heat generated.
  - c) There is increase in TS with increase in WS up to certain limit and further increase in WS decreases TS.
  - d) WS is inversely proportional to heat generated.
  - e) AF is directly proportional to heat generated.
  - f) The % E increases with increase in TRS and AF but decreases with increase in WS.
- iii) Most of the work has been done on similar alloys and less on dissimilar alloys.
- iv) CNC vertical milling machine can be used for experimentation work.
- v) Specially designed high speed steel tool with different TPP is used for FSW.
- vi) Most of the researchers uses Taguchi method and RSM for optimization of FSW process parameters.

### 4. CONCLUSION

Fig. 2. Graphical representation of influence of process parameters

The presented review focuses on the extensive efforts taken by previous researchers in the field of friction stir welding for optimization of process parameters. The effects of most influencing process parameters are discussed. It identifies future scope of friction stir welding in the field of aerospace and aircraft industries, marine, rail industries, etc. It is observed that friction stir welding has wide scope for joining similar and dissimilar materials.

# Fracture Behavior Analysis of a Finite Isotropic Plate with a Central Crack Under Various In-Plane Loading Using XFEM

Khubilal Khatri, Achchhe Lal

Department of Mechanical Engineering  
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

---

**Abstract:** This manuscript presents the fracture behaviour of an isotropic plate with a central crack having different angles subjected to various in plane loadings, such as tensile and shear loadings, through the mixed mode stress intensity factors (MMSIF). In this work, the crack is modelled using extended finite element method (XFEM) under plane strain condition using MATLAB. For the reliable and safe design of the structure, the prediction of the fracture behaviour of the crack configuration in a plate under different loading conditions through the MMSIFs becomes important. The study explains the critical level of the different crack configurations under different loading conditions.

**Keywords:** XFEM, MMSIF, plate with a central crack, in-plane loading.

---

## 1. INTRODUCTION

Under fatigue loading, the fracture of a structure may occur due to cracks initiation and their propagation from discontinuities such as flaws, edges, holes or pores, etc. The fracture behaviour analysis of such structure is necessary for avoiding unexpected failure. The types of loading, material properties, geometry of the structure, crack configuration, crack length, etc. play an important role in rate of crack propagation. In the presence of loadings, cracks configuration and their lengths influence the stress distribution and stresses around the crack tip very rapidly. The intensity of these stresses is responsible to propagate the cracks and hence, it is necessary to evaluate stress intensity factors against crack growth under external loadings for predicting and analysing the fracture behaviour of the structure. The life of a structure can be predicted through the knowledge of the criticality of the crack. Moreover, the fracture mechanics enhance the reliability and reduces the weight and the cost of the structure.

## 2. LITERATURE REVIEW OF THE ENABLERS OF KM ADOPTION IN SC

There are numbers of methods for calculating the critical SIFs of the cracked structure. In this direction, the SIFs have been evaluated using a complex mapping method (Bowie, 1954), boundary collocation method (Newman, 1971), boundary element method (Yan, 2006), FEM (Jabur, 2015 and Hajdu, 2014), mesh free methods (Nguyen, 2008), XFEM (Sharma, 2014 and Mohammadi, 2008) and the extended iso-geometric analysis (XIGA) (Bhardwaj et al. 2015). These methods have been used for evaluating the SIFs of plate with different crack configuration under

different loading conditions. The FEM is widely used for the failure analysis of the structure but it has some demerits using for evaluating fracture analysis of a structure with discontinuities such as cracks. The FEM requires original discretized mesh for the conformation with a discontinuity, i.e., crack in a plate.

Further, there is a requirement of fine meshing at the crack tip which is cumbersome and time consuming. Also, when the crack grows it requires further remeshing and there is an error in the results evaluated before crack growth and after crack growth for an element and the error maximizes at global level (Gustafsson et al. 2014). Such drawbacks are overcome by using XFEM. The XFEM is Galerkin method where the approximation space is enriched with additional functions. In this direction, many researchers have worked and the first, Belytschko and Black (1999) present a minimal remeshing FEM for crack growth. Also, M  es et al. (1999) present an improvement of a new technique for modelling cracks in the finite element framework using a standard displacement-based approximation enriched near cracks.

In this paper, the fracture behaviour of an isotropic finite plate with central crack under different crack configuration and loading conditions such as tensile and shear loadings is evaluated in terms of MMSIFs,  $K_I$  and  $K_{II}$ . The predicted results of the plate under different loading conditions are also compared. Section 1 is Introduction and the section 2 explains the brief review of the literature. The section 3 presents the XFEM methodology. Results and Discussion are described in Section 4. Further, the section 5 contains conclusions.

### 3. XFEM METHODOLOGY

For the modelling of the cracks, the XFEM displacement vector function for cracks by Mões et al. (1999):

$$u^h(x) = \sum_{i=1}^n N_i(x) [\bar{u}_i + \underbrace{H(x)a_i}_{\text{for crack face}} + \underbrace{\sum_{\alpha=1}^4 [\phi_\alpha(x) - \phi_\alpha(x_i)] b_i^\alpha}_{\text{for crack tip enrichment}}] \quad (i)$$

where,  $n$  is the sets of all nodes in the mesh,  $N_i(x)$  are conventional finite element nodal shape functions,  $\bar{u}_i$  is the displacements of the nodes associated with the continuous part of the solution and  $H(x)$  is Heaviside function.  $\beta_\alpha(x)$  is near-tip asymptotic functions for representing the singularity near the crack tip.

$$\beta_\alpha(x) = \left[ \sqrt{r} \sin\left(\frac{\theta}{2}\right), \sqrt{r} \cos\left(\frac{\theta}{2}\right), \sqrt{r} \sin(\theta) \cos\left(\frac{\theta}{2}\right), \sqrt{r} \sin(\theta) \sin\left(\frac{\theta}{2}\right) \right] \quad (ii)$$

where  $(r, \theta)$  are polar coordinates in the local crack tip coordinate system.

The displacement discontinuities in the interior part of the crack are modeled by an extrinsic function based on Heaviside function  $H(x)$ . It is defined as:

$$H(x) = \begin{cases} 1 & \text{if } \phi(x) \geq 0 \\ -1 & \text{otherwise} \end{cases} \quad (iii)$$

where,  $\text{sign}(\cdot)$  is signed distance function. The Heaviside function  $H(x)$  has the value  $+1$  above the crack and  $-1$  below the crack.

#### Evaluation of MMSIFs

The relationship between SIF and J-integral is:

$$J = \frac{K_I^2}{E^*} + \frac{K_{II}^2}{E^*}$$

where,  $E^* = \begin{cases} E & \text{for plane stress} \\ \frac{E}{1-\nu^2} & \text{for plane strain} \end{cases} \quad (iv)$

$$\text{Now, the J-integral: } J = \int_{\Gamma} \left( W \delta_{1j} - \sigma_{ij} \frac{\partial u_i}{\partial x_1} \right) n_j d\Gamma \quad (v)$$

where,  $W$ ,  $\delta_{1j}$ ,  $\Gamma$ ,  $\sigma_{ij}$  and  $u_i$  are the strain energy density, Dirac delta, area inside the contour, stress tensor and displacement field vector. Now, the cracked body has two states, present state and auxiliary state. Therefore, the J-integral can be written as:

$$J^{(1+2)} = J^{(1)} + J^{(2)} + M^{(1,2)}$$

$$\text{where } M^{(1,2)} = \int_{\Gamma} \left( W^{(1,2)} \delta_{1,j} - \sigma_{ij}^{(1)} \frac{\partial u_i^{(2)}}{\partial x_1} - \sigma_{ij}^{(2)} \frac{\partial u_i^{(1)}}{\partial x_1} \right) n_j d\Gamma \quad (vi)$$

where,  $J^{(1)}$ ,  $J^{(2)}$  and  $M^{(1,2)}$  are J-integrals for present and auxiliary states and interaction integral. Now by equation (6), we have:

$$J^{(1+2)} = J^{(1)} + J^{(2)} + \frac{2}{E^*} (K_I^{(1)} K_I^{(2)} + K_{II}^{(1)} K_{II}^{(2)})$$

$$\text{and } M^{(1,2)} = \frac{2}{E^*} (K_I^{(1)} K_I^{(2)} + K_{II}^{(1)} K_{II}^{(2)}) \quad (vii)$$

The stress intensity factors for the XFEM state  $K_I^{(1)}$  and  $K_{II}^{(1)}$  are evaluated by putting  $K_I^{(2)} = 1$  and  $0$  and  $K_{II}^{(2)} = 0$  and  $1$ , alternatively in the equation (vii), we have:

$$K_I^{(1)} = M^{(1, \text{Mode I})} E^* / 2$$

$$\text{and } K_{II}^{(1)} = M^{(1, \text{Mode II})} E^* / 2 \quad (viii)$$

where,  $M^{(1, \text{Mode I})}$  and  $M^{(1, \text{Mode II})}$  are interaction integrals.

### 4. RESULTS AND DISCUSSION

In this paper, the numerical examples are presented through XFEM with a computational program in MATLAB environment to evaluate the fracture analysis of MMSIFs  $K_I$  and  $K_{II}$  of an isotropic finite plate with a central crack subjected to different loading conditions. The results are validated with the available literature work and the new results are also presented.

#### 4.1 Validation

An isotropic finite plate subjected to tensile loading is first analysed. The material parameters are Young's modulus,  $E = 3 \times 10^7 \text{ Pa}$  and Poisson's ratio  $\nu = 0.3$ . The plane strain conditions are assumed for the problem. The dimensions of the plate are  $2 \text{ mm} \times 4 \text{ mm}$  with the normalized crack lengths of  $a/W = 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8$  and  $0.9$ , and a tensile stress of  $\sigma = 1.0 \text{ Pa}$  is applied to the top edge. The displacements along the y-axis are fixed at the bottom edge and the plate is clamped at the bottom left corner. The geometry, loading and boundary conditions are shown in Figure 1(a). The evaluated results are in good agreement with the results available in the literature as shown in Table I.

**TABLE I: The normalized Mode-I SIFs ( $K_I/\sigma\sqrt{\pi a}$ ) at different normalized crack lengths of an isotropic finite central cracked plate subjected to tensile loading**

$a/W$		0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9

### A plate with a central crack under tensile loading

In the examples, the XFEM approach is applied on an isotropic finite plate with a central crack under tensile ( $\sigma = 1$ ) loadings for evaluating MMSIFs,  $K_I$  and  $K_{II}$  w.r.t. different crack angles. The dimensions, material properties, crack angles, boundary conditions, etc. are same as mentioned earlier. The crack angles  $\alpha$  are  $0^\circ, 5^\circ, 10^\circ, 15^\circ, 20^\circ, 25^\circ, 30^\circ, 35^\circ, 40^\circ, 45^\circ, 50^\circ, 55^\circ, 60^\circ, 65^\circ, 70^\circ, 75^\circ, 80^\circ, 85^\circ$  and  $90^\circ$ . The line diagrams of the plate under tensile loading conditions are shown in the Fig. 1(a).

The Fig. 2 shows the fracture behaviour of a finite plate with a central crack under tensile loading in terms of MMSIFs,  $K_I$  and  $K_{II}$  w.r.t. different crack angles.

From Figure 2(a), for normalized crack length  $a/W = 0.1$  to 0.9, The Mode-I SIFs,  $K_I$ , are increased as crack lengths are increased but the gap between the all the curves are continuously decreased as the crack angle is increased from

$\alpha = 0^\circ$  to  $90^\circ$ . Also the Mode-I SIFs are decreased to zero (nearly). Therefore, the Mode-I SIFs of plate with a central under tensile loading is much critical when the crack angle is  $\alpha = 0^\circ$  for all the normalized crack lengths.

From Figure 2(b), for normalized crack length  $a/W = 0.1$  to 0.9, The Mode-II SIFs,  $K_{II}$ , are the lowest (zero) at  $\alpha = 0^\circ$  and  $90^\circ$  for all the normalized crack lengths and are the highest for the longest crack lengths. As the crack angle is increased from  $\alpha = 0^\circ$  to  $45^\circ$  and  $\alpha = 45^\circ$  to  $90^\circ$  the Mode-II SIFs are increased and decreased and decreased, respectively, for all the normalized crack lengths. Also the gap between the curves are increased and decreased from  $\alpha = 0^\circ$  to  $45^\circ$  and  $\alpha = 45^\circ$  to  $90^\circ$ , respectively. Therefore, the Mode-II SIFs of plate with a central under tensile loading is much critical at  $\alpha = 45^\circ$  for all the normalized crack lengths. For the crack propagation, the Mode-II SIFs play an important role for the safe and reliable design with integrity of the structure.

**Fig. 1. The line diagrams of a finite plate with a central crack under (a) tensile, (b) shear**

Fig. 2. Fracture behavior of a finite plate with a central crack under tensile loading in terms of MMSIFs, (a)  $K_I$  and (b)  $K_{II}$  w.r.t. different crack angles

#### 4.3 A plate with a central crack under shear loading

In the examples, the XFEM approach is applied on an isotropic finite plate with a central crack under shear ( $\tau = 1$ ) loadings for evaluating MMSIFs,  $K_I$  and  $K_{II}$  w.r.t. different crack angles. The dimensions, material properties, crack angles, boundary conditions, crack angles, etc. are same as mentioned earlier. The line diagrams of the plate under shear loading conditions are shown in the Fig. 1(b).

The Fig. 3 shows the fracture behaviour of a finite plate with a central crack under shear loading in terms of MMSIFs,  $K_I$  and  $K_{II}$  w.r.t. different crack angles.

From Figure 3(a), for normalized crack lengths  $a/W = 0.1$  to 0.2, 0.3 to 0.5, 0.6, 0.7, 0.8 and 0.9 The Mode-I SIFs,  $K_I$ , are increased from  $\alpha = 0^\circ$  to  $40^\circ$ ,  $0^\circ$  to  $35^\circ$ ,  $30^\circ$ ,  $25^\circ$ ,  $20^\circ$  and  $10^\circ$  as crack lengths are increased and are decreased

till  $\alpha = 90^\circ$  but the gap between the all the curves are continuously decreased as the crack angle is increased from  $\alpha = 0^\circ$  to  $90^\circ$ . Also the Mode-I SIFs are decreased to zero (nearly) at  $\alpha = 90^\circ$ . Therefore, the Mode-I SIFs of plate with a central under tensile loading is much critical at different crack angles for different normalized crack length but the crack angles between  $\alpha = 10^\circ$  to  $40^\circ$  are much critical for the shortest to the longest crack lengths.

From Figure 3(b), for normalized crack length  $a/W = 0.1$  to 0.2, 0.3 to 0.4, 0.5 to 0.8 and 0.9, the Mode-II SIFs,  $K_{II}$ , are increased from  $\alpha = 0^\circ$  to  $5^\circ$ ,  $0^\circ$  to  $10^\circ$ ,  $0^\circ$  to  $0^\circ$  to  $15^\circ$  and  $0^\circ$  to  $10^\circ$  and are decreased till  $\alpha = 45^\circ$  and  $\alpha = 50^\circ$  for  $a/W = 0.1$  to 0.4 and 0.5 to 0.9, respectively. Now, the Mode-II SIFs,  $K_{II}$ , are continuously increased from  $\alpha = 45^\circ$  to  $90^\circ$  for all the crack lengths. The Mode-II SIFs,  $K_{II}$ , are the least critical at  $\alpha = 45^\circ$  for all the crack lengths.

Fig. 3. Fracture behavior of a finite plate with a central crack under shear loading in terms of MMSIFs, (a)  $K_I$  and (b)  $K_{II}$  w.r.t. different crack angles

## 5. CONCLUSION

The fracture behaviour of an isotropic finite plate with different crack lengths and crack configuration under tensile and shear loadings is analysed using XFEM in terms of normalized MMSIFs and the following prediction regarding the fracture behaviour of the plate are mentioned:

Fracture behaviour of the plate with central crack under shear loading are much critical as compared to that of plate under tensile loading.

Under tensile loading, The MMSIFs are nullified when the line of the action of the crack is in the direction of the applied loading. The Mode-I SIFs dominant when the line of the action of the crack is perpendicular to the applied loading. The Mode-II SIFs come in picture only when the line of the action of the crack is in between the transverse and parallel to the applied loading.

Under shear loading, the MMSIFs dominant at nearby area of the line of the action of the crack and it is perpendicular to the applied loading for the longest crack. The Mode-I SIFs are nullified when the line of the action of the crack is in the direction of the applied loading and the Mode-I SIFs are the highest for the shortest crack when the line of the action of the crack is at  $\alpha = 45^\circ$ . The Mode-II SIFs are much critical when the line of the action of the crack is parallel to the applied loading. For the normalized crack lengths, The MMSIFs are the most critical when the plate are under shear loading. The Mode-II SIFs are much critical nearly at  $\alpha = 45^\circ$  for the shorter cracks when the plate is under the tensile loading in comparison.

# Recent Applications of Scanning Electron Microscope and its Variants in Industries: A Review

Hardik V. Naik, Vivek D. Kalyankar

Department of Mechanical Engineering  
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

---

**Abstract:** Advanced materials are applicable to various service conditions in addition to different environmental backgrounds. To avoid chances of failure, it is always recommended to understand the behavior and crystalline information of these materials. Hence this review work can be helpful for many researchers and industries for finding out appropriate approach. Advanced developments in material characterization with the help of literature review of scanning electron microscope (SEM) and its different approaches are discussed in this paper. Main focus is kept on the SEM used for surface topography, morphology, chemical composition, corrosion behavior, fracture tendency and crystallographic information of the materials. Over the last two decades electron backscatter diffraction (EBSD), field emission gun (FE), cryo-SEM and energy-dispersive x-ray spectroscopy (EDS) with the SEM have become a powerful approaches for the characterisation of advanced crystalline materials. This review work related to different approaches of SEM can be very helpful to various industries like aerospace, nuclear, marine and power plant as it provides different techniques of SEM to investigate advanced materials in various service conditions.

**Keywords:** Material characterization, SEM, advanced material, EBSD, FESEM

---

## 1. INTRODUCTION

By utilization of focused beams of electrons, SEM has become powerful tool for magnification purpose. SEM is useful to investigate surface topography, morphological information and elemental distribution by creating high resolution images by scanning of the surface of specimen and thus it becomes very valuable in technological advancement. The development of microscopes especially scanning electron microscopes has always been governed by one paradigm: their resolving power has to be enhanced. SEM is commonly used in the imaging of topographical properties and 90% of the research work is still dedicated to this characteristic or another of this application (Joy, 1997). Microstructure analysis is an important component for material characterization and has been an significant application of the SEM since energy dispersive X-ray spectrometers became available. SEM is a significant instrument that can deliver valuable information about the crystalline structure and various morphologies of advanced materials. However, if we see any object in three-dimensional (3D) view then it can create better understanding about that particular object. SEMs are limited to two dimensional images (2D) therefore it can provide only partial information about the materials. To understand truthfully the relationships between the phases and related properties, complex materials and morphologies are desirable to view unswervingly in 3D for better

investigation purpose. Recently, Yan et al. (2017) and Tafti et al. (2015) have demonstrated the single, multi view and hybrid techniques for 3D reconstruction of images of natural complex materials. Different approaches regarding SEM were attempted to identify the topography, morphology, chemical composition and crystallographic information of the materials. In addition, main limitation of SEMs are tendency to observe only solid and inorganic samples which are small enough to fit inside the testing chamber hence it is not suitable for liquid samples. So in general SEM, SEM-EDX, SEM-DIC, SEM-FIB and cryo-SEM are the different approaches during many research stated here for different applications. More categorised details based on different approaches and applications are stated in further section.

## 2. REVIEW OF SEM AND ITS DIFFERENT APPROACHES

SEM is used by many researchers in various areas as well as for understanding advanced materials. In this paper, different approaches are categorised to provide ready information on the basis of application point of view. Based on recent literature study related to engineering applications, it is observed that SEM is used for chemical composition, corrosion behavior, microstructure analysis, crack tendency and deformation study. Different approaches and applications of SEM considered in this work are mentioned in table 1.

Blochwitz and Tirschler (2000)	SEM	• Polycrystalline nickel	• Aero gas turbines as critical rotating components.	• Crack opening displacement     • Deformation behaviour

This review paper is aimed to summarize various approaches of SEM related to industrial applications. Recently, it is also observed that many unconventional applications of SEM and its different approaches such as to identify chemical composition, corrosion behavior, wear mechanism and crack morphology. SEMs are large, exclusive and must be contained in an area free of any possible environmental disturbance or vibration intercession. Many attempts have been made to combine

these properties but specific attempt can be made to carry out research in more than two combination at a time to obtain all properties by single apparatus. With the proper use, in depth understanding and selection of appropriate approach can lead to better utilization of material productivity, reduction in failure chances, development of new materials with better understanding and advancement in process capabilities.

### 3. OUTCOMES OF LITERATURE REVIEW

From the above literature review of SEM and its various approaches, it is observed that many industries like aerospace, marine, nuclear stations, power plants and bio-science are using SEM for surface topography, morphology and crystalline characterisation. SEM is very beneficial tool to identify the corrosion behavior and crack initiation as well as its propagation. Effect of corrosion was investigated by comparing the alternating current scanning electrochemical microscope (AC-SECM) current profiles with scanning kelvin probe force microscopy (SKPFM) potential profiles of H-charged AA2024 samples (Lafouresse et al., 2017). An effort was made to characterize corrosion behavior as well as microstructure study of A508-Alloy 52M interface region (Wang et al., 2014). Hydrogen detection is the key element to study corrosion behavior hence many researchers are using SEM to study hydrogen content at microstructural level. SEM was used for studying crack opening displacements (COD) of short cracks in situ in SEM after cyclic deformation at constant plastic strain amplitude (Blochwitz and Tirschler, 2000). Chemical composition, surface imaging and corrosion behavior of additional coating on AA2024-T3 after layer formation was investigated by SEM (Holguin et al., 2015). Surface topography and chemical composition are the basic outcomes SEM micrographs. Some of the important works related to surface topography (Marusakova et al., 2017), microstructure (Ding et al., 2017), crack behavior (Richter et al., 2001), chemical composition and morphology aspects (Helmer et al., 2016; Tao et al., 2017; Shi et al., 2017; Trdan and Grum, 2014) of different materials such as 2024 aluminum alloy (Lafouresse et al., 2017), Inconel 718 (Helmer et al., 2017), P122 Steel (Hara et al., 2013) and TC 21 titanium alloy (Shao et al., 2013) can be carried out by SEM. So in general, SEM can be used in many ways to avoid failures and to predict material tendency. Here, Fig. 1 and Fig. 2 shows the summarised details of different approaches and applications of SEM in industries respectively.

Fig. 1. Summary of approaches

Fig. 2 Summary of applications

### 4. CONCLUDING REMARKS

With continuous evolvement of advance materials and processes with an aim of improvisation in service life, SEMs are very useful tools for understanding different materials and their behavior in particular targeted service environment. In general, SEMs can investigate surface topography, morphological properties, crack behavior, corrosion tendency, chemical composition, phase deformation and wear characteristics of advanced material used in aerospace, marine, nuclear and power plant industry. Further, SEMs are useful in medical, bio science and metallurgy related applications too. SEMs are only having limitations of sample preparation and specific size limitation of solid samples. Even though the risk is minimal, SEM operators and researchers are counselled to observe safety precautions. Further, it is suggested to carry out literature study regarding different approaches and advancement in microscopy, macroscopy and spectroscopy so it can help many researchers to select appropriate tool and technique for investigations.

# Causes of Surface Defects during Surface Coating of Industrial Equipment by PTAW Welding Techniques

D.D. Deshmukh, V. D. Kalyankar

Department of Mechanical Engineering  
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

---

**Abstract:** Now a days it become a very crucial task to improve the life of equipment working in harsh environment. Various superficial materials and alloys with the aid of surface treatments have been applied on the equipment used for oil, gas and petrochemicals industries. Overlay is the process of depositing corrosion and wear resistance material on the substrate material by application of welding technology. Failure of the part at the vicinity of weld region occurred due to improper welding techniques or defects in the weld region such as porosity, blowholes, undercut and irregular HAZ. Weldment characteristics like penetration, bead geometry, reinforcement, depth of penetration and HAZ which are extremely important characteristics for structural integrity and homogeneity of the joint in the case of overlay process. The required composition, bonding and surface characteristics plays a vital role to improve the life of hard surface deposited on the substrate material. The accurate control of process capabilities are important to avoid the failure of hard surfacing during working. Therefore, depositing hard surfaces on the material which serves in harsh working conditions need to access critically. In this respect there has been considerable interest to access the characteristics and properties of hardfacing. However, retention of exact characteristics with required mechanical and tribological properties are depends on the processing of material during hardfacing. Considering these all facts this article presents the probable causes of defects occurring during hard surfacing with PTAW technique by practical approach.

**Keywords:** Surface defects, overlay, hardfacing, PTAW, Stellite, cracks

---

## 1. INTRODUCTION

Now a days, most of the parts of equipment used for power, alumina, nuclear and marine applications are failing due to abrasion, wear and corrosion. Abrasion, wear and corrosion are the processes which causes deterioration of material by gradual degradation and chemical reaction with their working environments. The possible threats of these deteriorations are components and machineries to fail during working. Moreover, these not only causes the aesthetic problems but also leads to cause the hazardous action, which increases the costs of repairing and rebuilding. In order to prevent the failure of components or equipment's used in various petrochemicals, marine, oil, nuclear, aerospace and power industries coating of superior material is applied on the parts which are directly exposing the aggressive environments (Madadi et. al, 2012). There are various methods to apply the coatings on the material; these techniques are probably based on characteristics and the behaviour of material in aggressive environments. The most common and practically applicable techniques to protect the material in very severe and harsh environments is to apply a metallic coating of outstanding resistant alloy on the materials (Bharath et. al, 2008). The selection of appropriate techniques plays a vital role in aggregating and maintaining the required characteristics of coating for long period. Moreover the parts are coated or repaired by superficial layer by the overlay techniques. Overlay is the

process of depositing corrosion and wear resistance material on the substrate material by application of welding technology. High energy density sources compromises rapid heating and successive quenching from the melt, resulting to fine microstructures and good improvement of mechanical, corrosion, or tribological properties (Bourithis et. al, 2002). Use of welding techniques can be more suitable as strong metallurgical bond being formed between the coating and the base materials. Hence, overlay processes are widely applied to enhance the corrosion and wear resistance of the substrate surface exposed to harsh working conditions, thus to improve and extend the service life of components.

The most commonly used welding techniques for the overlay are, submerged arc welding (SAW), tungsten inert gas welding or gas tungsten arc welding (TIG), oxyacetylene gas welding (OAW), plasma transferred arc welding (PTAW) and laser cladding (Balasubramanian et. al, 2009; Deng et. al, 2010). The application of these welding processes are commonly observed in petrochemical, chemical, steels, marine, power, oil and gas, alumina and aerospace industries (Deng et. al, 2010). Various researches on the coating characteristics and behaviour of material are going worldwide, to study the applicability and maintainability of these techniques for various kinds of material composition and pair. Failure of the part at the vicinity of weld region occurred due to

improper welding techniques or defects in the weld region such as porosity, blowholes, undercut and irregular heat affected zone (HAZ), weldment characteristics like penetration, bead geometry, reinforcement, and depth of penetration and HAZ which are extremely important characteristics for structural integrity and homogeneity of the joint in the case of overlay process. Superficial layers of the appropriate thickness free of cracks and with required mechanical and wear and tribocorrosion resistance properties may be obtained by suitable control of the process variables as the input process parameters plays a vital role in any welding processes.

The investigation of an overlay process is important to know how strongly certain parameters influence low distortion, less porosity and crack free surface with optimum value of hardness, penetration and reinforcement for a particular material composition. Considering these aspects it is necessary to understand the process and the causes of the defects. As, defects are the root causes for the equipment to fail because of perforation with only a small percent of weight loss of the entire structure. In this regard the process of welding overlay is studied with the effects of process parameters which are responsible for the surface defects and thus causing the failure of the part due to wear and tribocorrosion. The in-service modification and improvement of surface conditions of the equipment to avoid the failure is core area of investigation. In these respects, the causes of surface defects during surface coating of industrial equipment's by PTAW techniques are presented in this paper.

## 2. PTAW TECHNIQUE

The PTAW technique is a derivation of the plasma arc welding process. Use of non-consumable tungsten electrode is common in both the process and is located inside the torch. The PTAW uses powder as a filling material and inert gas, which is generally argon for its transportation to the arc area. PTAW technique has quite effectively been used as an outstanding surface alteration or treatment technique as a substitute to the other thermal spray processes (Bharath et. al, 2008; Deng et. al, 2010). Overlay obtained by the PTAW shows high quality, competitive wear and corrosion resistance and high retention of properties and characteristics of coating with better microstructural and stability of hardness at high temperature (Deng et. al, 2010). The PTAW overlays has a lower production cost and higher productivity compared to thermal sprayed coatings. The PTAW overlays are generally thicker than laser-induced overlays and there is a metallurgical bond between the substrate and the coating, improving their impact-resistance (Flores et. al, 2009a, b). Among the available techniques of overlay the most important differences lies in the welding efficiency and the weld plate dilution rates. The composition and properties of hardfacing are strongly influenced by the dilution obtained.

Control of dilution or penetration is important in overlay process, where typical low dilution is desirable (Balasubramanian et. al, 2009). The dilution obtain is much lesser in PTAW coatings. The PTAW presents high quality, competitive wear-resistance, and high stability of properties at high temperature (Deng et. al, 2010). The uses probable with PTAW are hardfacing and cladding to protect against severe conditions in service life like heat, abrasion, corrosion, erosion, adhesive and abrasive wear etc. It is also used to repair of worn out parts or build-up of mismatched parts. In practice, the parameters, which control the quality of the weld, are the gas flow rate (shield gas, plasma gas and carrier gas), the nozzle to work piece distance, the weld current and the welding speed.

Recently, PTAW technique has gain tremendous attraction for deposition of superior alloys on the substrate material to impart corrosion and wear resistance thus improves the service conditions. Superior alloying materials always imparted the surface modification; Co and Ni based alloys are applied in numerous industries, including chemical and fertilizer plants, nuclear and steam power plants, pressure vessel, as it is convenient and practical. In this regard the process of overlay is studied with the effect of process parameters which are responsible for the producing tough and harder coating without any defects. The main objectives of this paper are to reveal the exact causes of surface defects occurring during processing and to address the issues related to overlay related to PTAW. The causes of surface defects are evaluated by varying the process parameter between the allowable limits.

## 3. EXPERIMENTATIONS

To carry out the investigations, PTAW machine available with the KOSO India Pvt. Ltd. Ambad, Nashik, a valve manufacturing industry, made by Primo automation Ltd., is utilized which is fully automated. This technique has been in use for the surfacing of parts i.e. valve seat, collars, sleeve and couplings, employed for the surfacing of valves and components. Deposition is prepared on the surface of plate of thickness 16 mm in the form of multitrack layers by varying the process parameters. The electrode negative (DCEN) according to the welding process specification (WPS) ASME21, with position of groove 1G. Tungsten electrode size of 4 mm diameter (2% Throated Tungsten), torch orifice diameter 25mm, Industrially pure argon (99.99%) is used at a constant flow rate of 15 L/min for shielding, 2.5 L/min for centre, and 3 L/min for powder feeding.

The process parameters selected for the experimentations are, heat producing element i.e. transferred arc current (Amp), welding speed corresponding to travel speed (mm/min), filler material flow rate i.e. powder feed rate (gms/min), torch frequency i. e. oscillation speed (mm/min) and torch to workpiece distance i. e. stand-off distance

(mm). The effects of process parameters with defects obtained are observed and examined by visual inspections and dye penetration test. The substrate material and the surfacing alloy used for the experimentation is explained in following subsection.

### 3.1 Substrate material

The material used for the experimentation is based on the application of valve, pressure vessel, chemical processing industry etc. which should possess the weldability, good corrosion, wear and abrasion resistance properties. Material which is exposed to severe working conditions made up of, stainless steels, duplex stainless steel, Inconel, low alloy steels, high alloy steel and plain carbon steels etc. Stainless steels and Inconel of various grades are commonly employed for the manufacturing of valve, valve seats, collars and sleeves. However the area of base metal which is more susceptible to corrosion is coated by superficial layers of more corrosion resistant surfacing alloys. Most of the components applied for the marine environments are made up of duplex stainless steels, stainless steels and Inconel. Based on these points the material for the present investigation is selected as 316L stainless steels, which has widespread use in industries such as oil and gas pipelines, petrochemical chemical pumps, pressure vessels and chemical processing equipment.

### 3.2 Surfacing alloy

Cobalt based alloys are widely employed as wear-resistant hardfacing materials for combating wear in corrosive mediums and find applications in marine, gas, oil, petrochemicals, power, chemical, medical and food processing industries. Stellite alloy has nominal composition of Co - 28 Cr - 4W - 1.1C (wt. %). Stellite alloys which are commonly used as hardfacing materials in a variety of industrial applications, as they are known to possess high hardness at high temperature, good resistance to sliding wear under elevated contact pressure and good corrosion resistance. Stellite 6 is a cobalt-base alloy which is resistant to wear and corrosion and retains these properties at high temperatures (Madadi et. al, 2012). Stellite 6 is a useful hardfacing alloy in which chromium provides corrosion resistance while carbides add strength to the alloy (Singh et. al, 2014). From the literature it is found that Stellite 6 has excellent resistance to cavitation and corrosion, outstanding self-mating, anti-galling characteristics and it is used in valve, valve seats, plugs, pumps, bearings, shafts, erosion shields, rotors, etc.

## 4. RESULTS AND DISCUSSIONS

By varying the selected process parameters in between the available ranges the deposition is prepared in the form of layers on the substrate material. The weld bead geometry its appearance, surface irregularities and defects are examined by visual inspection and dye penetration test. Whereas, the

occurrences of crack generation on the surface of overlay are due to sudden change in temperature of surfaces. As the cooling rate changes, the Co based powder coating generates cracks on the surface of steels as shown in Fig. 2. Moreover, following inferences are drawn during operation and examination of overlay surface by dye penetration test.

1. For torch oscillation speed less than 450 mm/min, the bead appearance and contours were not so smooth and very narrow bead was obtained. When the oscillation speed was greater than 850 mm/min, wider bead width and smaller reinforcement height were observed. During the investigations it is observed that, higher torch oscillation frequency, the torch covers wider region of substrate material resulted in higher dilution with the gradual increase in width of deposition with torch oscillation frequency. Consequently at higher torch oscillation frequency, reinforcement decreases. As oscillation speed increases, the mean value of width of oscillation of torch also increases. In contrast, very thin layer of the deposited surface with spatter and blowholes are observed corresponding to high oscillation speed and lower powder feed rate. A very narrow and irregular weld bead and small deposition reinforcement is observed corresponding to the low oscillating speed. The chances of blowholes in the coating are higher at higher oscillation speed as shown in Fig. 1 than at lower oscillation speed.
2. If the powder feed rate was lower than 08 g/min, over melting of base metal and overheating of tungsten electrode were noticed. When the powder feed rate increases than 20 gm/min, the width and reinforcement of deposition increases. Also the weld bead formation was not smooth owing to incomplete melting of powders. Because, the amount of heat energy supplied at that instant is being utilised for melting of powder and forming a molten pool with possibly less melting of substrate material. This results less melting of substrate material, provided that the current supplied is sufficient to melt the powder supplied at that instant. It is also observed that, there is variation in deposition parameters with the powder feed rate and it is identified that cross-section area of deposition rises with the increase in powder feed rate and due to this the melting of substrate material decreases. Lower powder feed rate and higher current produces spatter and undercut on the surface with uneven layer of deposition as shown in Fig. 3. Whereas, higher powder feed rate reduces the melting of substrate material and causing less bonding in the deposited layer.
3. If the transferred arc current was less than 100 A, the incomplete melting of powders and lack of penetration is observed on the substrate surface. For

**Fig. 1 Overlay showing blowhole**

**Fig. 2 Overlay showing crack**

**Fig. 3 Overlay showing spatter and discontinuity**

**Fig. 4 Overlay showing spatter and less penetration and narrow bead width**

**Fig. 5 Overlay showing blowhole and uneven reinforcement**

**Fig. 6 Overlay showing blowhole and over melting of substrate at starting**

the transferred arc current greater than 180 A, the undercut and spatter are noticed on the weld bead surface. This is attributed due to the fact that the heat energy supplied for producing the arc at constrictor nozzle increases as transferred arc current. The prominent effects of heat supplied on melting of substrate materials is found in the investigations. With

the increasing current, the melting of substrate material increases leading to complete fusion of the powder supplied at that instant with the substrate surface causing higher deposition and undercuts. Consequently, at lower current the heat energy supplied is less causing incomplete melting of powder and less bonding with the overlaid material.

4. If the travel speed was less than 100 mm/min, there was an over deposition of weld metal and higher reinforcement height was observed. Travel speed corresponds to relative displacement of material surface per unit time to the torch or arc current. Higher travel speed greater than 180 mm/min reduces the time availability for deposition and thus producing very thin layer with zig zag pattern. Also less bonding and incomplete penetration is observed on the overlaid surface at higher travel speed. Which resulted in spatter and cut-off of deposition as shown in Fig. 4. Whereas, lower travel speed less than 100 mm/min shows over deposition of filler material as well as over melting of substrate surface resulted in deeper penetration and very thick weld bead with undercut and spatter as shown in Fig. 5. Thus, appropriate travel speed is necessary to create the bonding between substrate material and overlaid layer.
5. For stand-off distance less than 5 mm the bead appearance and contours were not so smooth and very narrow bead was obtained as shown in Fig. 6. When the stand-off distance was greater than 14 mm wider bead width and smaller reinforcement height with less melting of substrate material was observed. It is observed that the percentage melting of substrate decreases as the stand-off distance increases giving less concentration at particular point as lateral spread of arc concentration increases with stand-off distance. It is identified that, because of increase in arc length the constrictor arc diverge and the heat input supplied to the wider region of substrate material instead of directing on a lesser area. Which causes lower reinforcement and wider deposition width. Further, increase in stand-off distance, some amount of voltage rise takes place resulting in more heat input. It is also observed that the deposition width increases very slightly up to the mean level and again start to falls. Layer reinforcement also decreases with the increase in stand-off distance. This is attributed due to the fact that the change in stand-off distance did not vary the energy supplied to substrate material but the lateral spread of powder depositions increases due to changed diameter of energy density distribution from the plasma arc on the substrate material.

## 5. CONCLUSIONS

Surface overlay processes are widely used for the improvement in wear, tribocorrosion and mechanical properties of substrate surfaces which are exposed to severe environmental condition. Use of appropriate overlay technology is of prior importance to achieve desired properties of the surface. The realization of the economic advantage of increased wear resistance by providing a metal deposit on a relatively low cost substrate has spurred the growth of hardfacing over the last half century. Failure of

the components due to surface deterioration is the main focusing issue for the various industrial equipment's such as, power, marine, oil and chemical industry. The cost of failure of the equipment is not only related to the failure of the specific parts but it leads to decrease the productivity of the plant also in many cases it leads to hazardous action. To avoid the hazards due to failure of parts it is necessary to investigate the possible failure mechanism and to concentrate the root cause of the process. From the present investigations, it is observed plasma transferred arc welding overlay process is greatly affected by the influence of process parameters. The control of process parameters such as welding speed, powder feed rate, oscillation speed, transferred arc current and post and pre heat treatments are very important. In this investigation, an attempt is made to assess and investigate the causes of surface defects by proper controlling the input process parameters and systematic investigations. Now a days different types of stainless steels have been in use for the application where material exposes to severe condition, duplex stainless steel is widely used for various applications, tubing for heat exchanger, oil and gas, petrochemical, pulp and paper, and pollution control industries. The performance of a part is often determined by the properties of welded joints rather than those of main materials in welding processes. Therefore, it is very important to select proper welding process parameters employed in the process to improve weld qualities. The possible outcomes are useful for the industries where, surfacing of components are carried out by PTAW. Usually for power, oil and gas, petroleum industrial applications where, work related to steels rebuilding and refurbish or upgradation of properties takes place.

## 6. FUTURE SCOPE

The use of PTAW is tremendous in industry applications, however, the research on the technique considering applicability, effectiveness, efficiency, quality of overlay deposits and material applications are limited and very scared. Various superficial alloys can be implemented for the deposition, such as Stellite of various grades, Ni based alloy, Co base alloy, WC based alloys, Ti based alloy, TiN alloy etc., with the cheap base material. The superiority, effectiveness and applicability of various combination of materials need to be evaluated and examined by experimental investigations coupled with advanced techniques. Now a days different types of stainless steels have been in use for the application where material exposes to severe condition, duplex stainless steel is widely used for various applications, tubing for heat exchanger, oil and gas, petrochemical, pulp and paper, and pollution control industries. The microstructure, wear and abrasion resistance of the various material exposed to erosive, corrosive and abrasive media can be done by experimental investigation and in situ observations. It is very important to investigate the tribo-corrosion behavior of coating and to select the

proper welding process parameters employed for the process to improve weld qualities in the overlay. The applications of modern techniques, investigations and analysis plays a vital role to understand and evaluate the performance of the coating in the aggressive environment. Further investigations will be required in this field to explore the applicability and effectiveness of the process.

**Abstract:** The aim of this research paper is to minimize the tool wear of cutting tool by image processing during turning AISI 4340 steel. Taguchi  $L_{27}$  orthogonal array (OA) is used for conducting the experimentation. Cutting Environment, feed rate, nose radius, depth of cut and tool type are the input parameters for turning process. The output parameter is tool wear. Machine tool condition in terms of spindle vibration is considered as a noise factor (uncontrollable factor) to make design robust. Cutting speed is kept constant (210 m/min). Image processing module in MATLAB 13 software is used to measure the wear of tool. A special algorithm is designed for it. The results of ANOVA for Tool wear indicate that depth of cut is the most significant machining parameters in affecting the tool wear followed by feed rate, nose radius, cutting environment, and tool type. The main effect plot of S/N ratio, the optimal machining parameters are the cutting environment at level 3 ( $A_3 = MQL$ ), nose radius at level 3 ( $B_3 = 1.2$  mm), feed rate at level 3 ( $C_3 = 0.35$  mm/rev), depth of cut at level 1 ( $D_1 = 0.5$  mm), and tool type at level 3 ( $E_3 =$  coated (CVD)) or  $A_3B_3C_3D_1E_3$  in short. Tool wear is optimized up to 0.042 mm. Conformity test revealed that the predicted and experimental values of Surface roughness are within the range given by confidence interval.

**Keywords:** Optimization, Image processing, turning process, Taguchi, ANOVA

## 1. INTRODUCTION

Demand of customers regarding quality of product and its production rate is increasing. To stand in the market with strong root manufactures have to fulfill this demand within the time. This can be achieved by the optimization of the process. Manufacturing process often involves optimization of machining parameters in order to improve product quality as well as to enhance productivity. In metal cutting process, especially turning, milling process, besides the basic cutting process parameters viz. cutting speed, feed rate, depth of cut, tool geometry, environment of cutting and the type of tool plays an important role to decide the performance of quality characteristics.

Hari Singh *et al* [1] (2005), in this paper, a design of experiment based approach is adopted to obtain the optimal setting of turning process parameter that may yield optimum tool wear. The predicted optimal values of flank wear width crater wear depth of coated carbide tool while machining the EN 24 steel are 0.172mm and 0.244 microns respectively. Shiv Sharma *et al* [2] (2014), this paper stated a Fuzzy logic modeling and multiple performance optimization in turning GFRP composites using desirability function analysis. The input variables are cutting speed, feed rate and depth of cut. The responses are surface roughness, metal removal rate and tool wear. The average

percentage error in fuzzy logic prediction obtained as 2.74 %, 12.67 % and 3.06 % for Ra, MMR and VB respectively. Debaprasanna Puhan *et al* [3] (2013), this paper stated hybrid approach for multi-response optimization of non-conventional machining on AISiCp MMC. The influence of discharge current, pulse duration, duty cycle, and flushing pressure on material removal rate, tool wear rate, surface roughness are studied. It is found that pulse duration, duty cycle, discharge current and flushing pressure contribute significantly to the multiple performance characteristics.

Hari Singh *et al* [4] (2003), Araştırma Makalesi *et al* [5] (2006), Nilrudra Mandal *et al* [18] (2011), these paper stated the effect of cutting speed, feed rate, depth of cut on flank wear, crater wear, tool wear during turning of EN24 steel, AISI 304 Austenite stainless steel, AISI 4340 steel respectively. Mr. Ballal Yuvaraj *et al* [6] (2012), this paper used the Taguchi method to find a specific range and combinations of turning parameters like cutting speed, feed rate and depth of cut to achieve optimal values of response variables like surface finish, tool wear, material removal rate in turning of Brake drum of FG 260 gray cast iron Material. It is a scientifically disciplined mechanism for evaluating and implementing improvements in products, processes, materials, equipments and facilities.

## 2. TAGUCHI PHILOSOPHY

Among the available methods, Taguchi design is one of the most powerful DOE methods for analyzing of experiments. It is widely recognized in many fields particularly in the development of new products and processes in quality control. The salient features of the method are as follows:

- It is a simple, efficient and systematic method to optimize product/process to improve the performance or reduce the cost.
- It helps arrive at the best parameters for the optimal conditions with the least number of analytical investigations.
- It is a scientifically disciplined mechanism for evaluating and implementing improvements in products, processes, materials, equipments and facilities.
- It includes the noise factor and makes the design robust.
- It is low cost experimentation

There are three Taguchi quality characteristics:

### 1. Smaller the better (SB) –

It is a non-negative measurable characteristic that has an ideal state or target of zero.

$$S/N = -10 \log \left( \left( \frac{1}{n} \right) \sum y^2 \right) \quad (1)$$

### 2. Nominal the best (NB) –

It is a measurable characteristic with a specific user defined target value.

$$S/N = -10 \log \left( \frac{\hat{y}}{s^2} y \right) \quad (2)$$

### 3. Higher the better (HB) –

It is a non-negative measurable characteristic that has an ideal state or target of infinity.

$$S/N = -10 \log \left( \left( \frac{1}{n} \right) \sum \frac{1}{y^2} \right) \quad (3)$$

## 3. MATERIAL AND EXPERIMENTATION

### 3.1 Test Specimen (Workpiece):

The work material used for the present study is AISI 4340 steel (diameter 50 mm and length 80 mm). In industries, this material is regularly used for manufacturing of hydraulic equipments like split bush. It is high tensile alloy steel well-known for its wear resistance properties and are suitable where high strength properties are required.

TABLE 1: Chemical composition of AISI 4340

C	SI	MN	S	P	Cr	Mo	Ni
0.36/ 0.47	0.10/ 0.35	0.45/ 0.70	0.040 max	0.035 max	1.00/ 1.40	0.20/ 0.35	1.30/ 1.70

### 3.2 Cutting Tool

The uncoated & coated carbides tool materials are used for improving the productivity. The coated carbide tool reduces wear and tear between tool insert and workpiece. In the present work, the uncoated and coated (Physical vapour deposition-PVD and Chemical vapour deposition-CVD) carbide inserts are used for turning AISI 4340 steel. In market the inserts of standard nose radius (from 0.4 to 1.6 mm) are available. ISO catalog Number of selected carbide inserts are CNMG120404, CNMG120408; and CNMG120412.

### 3.3 Experimentation

The experimentation was performed on CNC SPINNER15 lathe machine as shown in fig 3. Test pieces of size 50mm×80mm were cut from AISI 4340 steel bar. The five input variables used in this study were Cutting environment, Nose radius, Feed rate, Depth of cut and Tool type. Spindle vibration was taken as a noise factor. Cutting speed was kept constant.

TABLE 2: Process Parameters And Their Levels

Process Parameters	Level-1	Level-2	Level-3
Cutting Environment ( A )	Dry	Wet	MQL
Nose radius (mm) (B)	0.4	0.8	1.2
Feed rate (m/rev) (C)	0.15	0.25	0.35
Dept of cut (mm) (D)	0.5	1	1.5
Tool type (E)	Uncoated	PVD	CVD
Spindle vibration (m/s ² ) (NF)	1.7	4.3	6.9

Fig. 1 Experimental Set Up

#### 4. MEASUREMENT OF TOOL WEAR

Cutting tool wear is measured by the image processing method in MATLAB software. This is a non conventional

method used for edge detection of tool. A special algorithm is made to detect the edge of the tool as shown below

##### 4.1 Steps of Wear Measurement

###### Step 1: Read the image:

The tool wear image is captured by high definition CCD camera and is fed to the image processing in MATLAB software as an input.

###### Step 2: Processing of image:

To enhance the good quality of the image, a self developed shadow removing algorithm written in MATLAB and the Canny edge detection algorithm in digital image processing toolbox for MATLAB was used for the segmentation of the wear area in the captured image.

- The Canny edge detection algorithm was preferred over other edge detection methods because of its double thresholds feature that allows detection of both strong and weak edges.
- The detected weak edges are included in the output only if they are connected to strong edges.
- The captured image is then saved in 'jpeg' format for further processing.
- Wear detection: edge detection technique is used for wear measurement.

There are various methods used for edge detection like Sobel, Prewitt, Robert; and Canny. Out of these methods, Canny is used as it gives the best performance. It also removes the noise present in the image.

###### Step 3: Wear measurement:

Wear measurement is done in terms of flank wear by using flank wear conditions. A new tool wear measurement technology is proposed and developed by image processing method. Software in MATLAB environment is developed to verify the suggested image. This method can extract the wear area based on a 2D image process algorithm.

**Fig. 2: Tool Wear Measurement By Edge Detection Technique**

The experiments are conducted as per Taguchi method and experimental data is collected for tool wear. Tool wear is measured for each level of spindle vibration and average value is taken as the final value shown in table

**TABLE 3: Experimental Data For Tool Wear And Its S/N Ratio**

Run	Tool Wear_NF ₁	Tool Wear_NF ₂	Tool Wear_NF ₃	Average Tool Wear	SN ratio Tool Wear

## 5. DATA ANALYSIS

Data analysis has been carried out by the procedural hierarchy as shown below.

- Selection of equation for Signal-to-Noise ratio (S/N ratio) according to the objective of optimization. As the objective is to minimize the tool wear, therefore smaller the better (SB) equation (1) has been selected for S/N ratio.
- Computation of S/N ratio for each run. Tool wear with S/N ratio is listed in table 3.
- Calculations of response table for mean S/N ratio at each level of tool wear to identify the rank of level table 4 & fig 6
- Selection of optimal setting from mean S/N ratio.
- Computations of ANOVA to find the significance and contribution of each parameter on tool wear.
- Calculation of predicted value of tool wear by predicted additive model.
- Verification of predictive model by confirmatory test.

**TABLE 4: Response table for Signal to noise ratio**

Level	Cutting environment	Nose radius	Feed rate	Depth of cut	Tool type
1	-13.552	-14.612	-15.293	-11.651	-11.197
2	-11.860	-12.014	-12.620	-11.282	-11.926
3	-10.348	-9.134	-7.847	-12.827	-12.636
Delta	3.204	5.477	7.446	1.546	1.439
Rank	3	2	1	4	5

**TABLE 5: Analysis of variance for S/N**

Process parameters	DOF	SOS	MSOS	F	P	% Contribution
Cutting environment (A)	2	0.005111	0.002556	8.49	0.000	10.05
Nose radius (B)	2	0.004304	0.002152	7.15	0.000	8.46
Feed rate (C)	2	0.010758	0.005379	17.87	0.000	21.16
Depth of cut (D)	2	0.027686	0.013843	45.99	0.000	54.45

Residual Error	4	0.001204	0.000301			2.37
Total	26	0.050849				100.00

**Fig. 3: Main Effect Plot of Signal To Noise Ratio**

### 5.1 Predicted Value of Tool wear (mm)

Optimal value of output parameter can be predicted by additive model

$$\mu_{pred} = \bar{Y} + \sum (\bar{Y}_i - \bar{Y}) \quad (4)$$

$$\begin{aligned} \mu_{TW} &= Y_{TW} + (A_3 - Y_{TW}) + (B_3 - Y_{TW}) + (C_3 - Y_{TW}) + (D_1 - Y_{TW}) + (E_3 - Y_{TW}) \\ \mu_{TW} &= 0.123 + (0.107 - 0.123) + (0.107 - 0.123) + (0.104 - 0.123) + (0.097 - 0.123) + (0.115 - 0.123) \\ &= 0.0401 \text{ mm} \end{aligned}$$

Error variance  $V_e = 0.000301$

Therefore,

$$CI = \pm 0.018$$

The 95% confidence interval of the population is:  $[\mu_{TW} - CI] < \mu_{TW} < [\mu_{TW} + CI]$

$$0.0223 < 0.0401 < 0.0579$$

**TABLE 6: Confirmatory Experiments for Tool Wear (mm).**

Sample	Tool Wear (mm)		
	NF1 1.7 m/s ²	NF2 4.3 m/s ²	NF3 6.9 m/s ²
1	0.0338	0.0346	0.0588
2	0.0339	0.0368	0.0549
3	0.0342	0.0357	0.0568
Average	0.0340	0.0357	0.0568
Total Average	0.0422		

## RESULTS

The results of ANOVA for Tool wear indicate that depth of cut is the most significant machining parameters in affecting the tool wear followed by feed rate, nose radius, cutting environment, and tool type. Based on the above discussion and the main effect plot of S/N ratio, the optimal machining parameters are the cutting environment at level 3 ( $A_3 = \text{MQL}$ ), nose radius at level 3 ( $B_3 = 1.2 \text{ mm}$ ), feed rate at level 3 ( $C_3 = 0.35 \text{ mm/rev}$ ), depth of cut at level 1 ( $D_1 = 0.5 \text{ mm}$ ), and tool type at level 3 ( $E_3 = \text{coated (CVD)}$ ) or  $A_3B_3C_3D_1E_3$  in short

**TABLE 7: Values of Process Parameters at Optimum Level**

Process Parameters	Code	level1	level2	level3
Cutting Environment	A	DRY	WET	MQL
Nose radius(mm)	B	0.4	0.8	1.2
Feed rate (mm/rev)	C	0.15	0.25	0.35
Dept of cut (mm)	D	0.5	1	1.5
Tool type	E	Uncoated	PVD	CVD

## 6. CONCLUSION

The Taguchi method is successfully applied in this study to find optimal setting for turning AISI 4340 steel. The results are discussed as follows:

- 1) The single-objective problem is solved with the application of Taguchi Analysis.
- 2) Quality characteristic Tool Wear is optimized to 0.042 mm

- 3) Optimal parameter setting for turning AISI 4340 steel is ( $A_3 B_3 C_3 D_1$  and  $E_3$ ) i.e. cutting environment=MQL, nose radius=1.2 mm, feed rate =0.35 mm/rev, depth of cut = 1.5 mm, and PVD coated cutting tool.
- 4) Conformity test shows that the predicted and experimental values of Tool Wear are within the range given by confidence interval.

# Advances in Abrasive Flow Machining Technology for Fine Finishing: A Review

Pratik A. Patil, Sachin K. Patil

Department of Mechanical Engineering  
Rajarambapu Institute of Technology, Sakharale, Maharashtra, India

---

**Abstract:** The fine surface finish is one of the prime requirements in various finished components through conventional machining processes like grinding, lapping, polishing and super finishing processes. Many industries are striving hard to get the desired surface finish since they are using highly complex shaped and stringent property materials and this has increased the scope of research in non-conventional processes. Abrasive Flow Machining (AFM) is one of the non-conventional finishing processes in which a semi-solid medium consisting of a visco-elastic polymer and abrasive particles mixed in a definite proportion. This media is extruded under pressure through or across the surface to get the required finish. In this paper current research advances in abrasive flow machining are discussed thoroughly, also author has tried to identify the research gap in the past work. The review paper opens new research avenues for further work.

**Keywords:** Abrasive flow machining, Magnetic abrasive finishing, Magnetic abrasive flow machining, Magneto rheological abrasive flow finishing

---

## 1. INTRODUCTION

Technologies in modern industries are getting highly advanced, thus the machining processes involved are required to be more precise and efficient to obtain a quality product whilst maintaining high productivity. Life and functionality of a product is directly influenced by its surface finish. Now-a-days, nonconventional materials like Titanium alloys, Tungsten, various composites etc. are used widely in industries because of their special properties such as high strength, high hardness, better wear resistance, high toughness etc. However these properties make them difficult to be machined. Various conventional finishing processes such as grinding, honing, lapping etc. are used in industries for long time, but they are limited to particular geometries and cannot be applicable to complex geometries and intricate profiles to machine to high level finish as required during the operation of these components. Some advanced finishing processes like AFM (Abrasive flow machining), MAF (Magnetic abrasive finishing), and CMP (Chemical mechanical polishing) etc. can be employed for finishing these materials (Jain, 2004). The material removal mechanisms of abrasive fine-finishing technology are quite different from those of grinding. In Abrasive fine-finishing technology the stock removal capability is far lower than grinding, and thus it is helpful in maintaining accurate dimensional accuracies. It does not utilize grinding wheels, and the cutting speed is significantly lower than in grinding (Fukuo et. Al. 2016). Extrude Hone Corporation of USA in 1960s developed the concept of AFM to finish aerospace components to the required accuracy. Today abrasive flow machining is considered as one of the best method for finishing of complex geometries not accessible by the

conventional finishing tools. Many researchers are consistently working in this are for the betterment of AFM process. This article includes detail review of current research trends in AFM process on the basis of Advanced setups of AFM process, Different combinations of Abrasive media and the applications of advanced setups in field of Agriculture, Engineering and biomedical applications.

## 2. ABRASIVE FLOW MACHINING

The mechanism of material removal in AFM is as follows:

- a. Initially, the material is ploughed by the fine abrasives that come in contact with the work material as they rub over the metal surface with high pressure. The material flow occurs in the direction of motion of abrasive particles as well as in lateral direction, resulting into the formation of lips.
- b. At the lips, work hardening is noticed due to the rubbing action of the continuous flowing abrasive particles which are also responsible for intense plastic flow with considerable stress concentration.
- c. The further flow of abrasive particle causes continued work hardening which results in embrittlement and fragmentation of the lips into microchips. (Gorana, Jain and Lal, 2006).

Abrasive flow machines are classified into 3 types based on motion of abrasive media.

1. One-way AFM: Abrasive media is forced in one direction as shown in Fig. 1(a) (Rhoades, Kohut and Nokovich, 1994).

2. Two-way AFM: Abrasive media reciprocates to and fro as shown in Fig. 1(b) (Rhoades and Kohut, 1991).
3. Orbital AFM: Small orbital vibrations are applied to the work piece shown in Fig. 1(c) (Gilmore and Rhoades, 2001).

Abrasive flow machining is influenced by number of parameters which are classified as machine parameters, work piece parameters and medium parameters (Williams and Rajurkar, 1989). Some of the parameters are listed below.

(a) One way AFM process

(b) Two way AFM process

(c) Orbital AFM process

Fig. 1. Types of Abrasive flow machining processes

TABLE 1: AFM process parameters

Workpiece parameters	Machine Parameters	Medium Parameters
Hardness	Number of cycles	Type of abrasive
Material	Extrusion Pressure	Type of polymer carrier
Surface Texture	Flow Volume	Additives
Length of passage	Media flow speed	Concentration of abrasives

### 3. AN OVERVIEW OF DEVELOPMENTS IN ABRASIVE FLOW MACHINING SETUPS

Abrasive flow machining has plenty of advantages listed as below:

- 1) Surface modification in texturing and topography.
- 2) Damage-free surface generation without a heat-affected zone.
- 3) Enhancement of surface integrity and the creation of compressive residual stresses in most of cases.
- 4) Improvement of geometrical accuracies, such as roundness, profile, etc.
- 5) Enhancement of visual factors such as uniformity, light reflection, brightness, etc. (Denkena, Kohler and Schindler, 2008).

Many researchers have investigated AFM and have concluded that the process is having low Material removal rate. To enhance the performance of AFM process many researchers have developed the hybrid machining processes in which various machining processes are combined with AFM process to achieve the higher MRR and required surface finish in lesser time. Some of the recently developed setups are highlighted in this section.

Singh and Shan, 2002 developed Magneto Abrasive Flow Machining (MAFM) process to improve the surface roughness by applying a magnetic field around the work piece. Magnetic flux density, volume flow rate, number of cycles, medium flow volume, abrasive grit size and abrasive concentration were the identified significant parameters. Improved surface finish and material removal rate is observed in MAFM over AFM.

**Fig. 2. Magnetic abrasive flow machining**

Main parts: (1) cylinder containing medium; (2) flange; (3) nylon fixture; (4) workpiece; (5) eye bolt; (6) hydraulic press; (7) auxiliary cylinder; (8) modular relief valve; (9) piston of hydraulic press; (10) directional control valve; (11) & (12) manifold blocks; (13) electromagnet. (Singh and Shan, 2002).

Rahul et al. [11] have developed Electrochemical and centrifugal force assisted abrasive flow machining process with an objective to enhance efficiency and quality of finish surface. The effects of parameters such as voltage, salt concentration, RPM etc. and constant parameters such as number of cycles, extrusion pressure on material removal has been investigated. The results depicted that better surface finish can be obtained with less extrusion pressure which can reduce damage of fragile parts. Also 70-80 % machining time can be reduced.

**Fig. 3. Hybrid electrochemical and centrifugal force assisted AFM process**

Jha and Jain developed Magnetorheological Abrasive Flow Finishing (MRAFF) process for finishing intricate details of a part. In this magnetorheological polishing fluid equipped with carbonyl iron powder and silicon carbide abrasives are mixed with viscoelastic base grease and mineral oil used to finish workpieces. 25-30 % improvement was observed in surface finish at high magnetic field application. The below mentioned figure is the schematic of magneto rheological abrasive flow finishing setup.

**Fig. 4. Magnetorheological abrasive flow finishing process, a) Mechanism of Magnetorheological abrasive flow finishing process; b) Change in rheological behaviour of MR-polishing fluid during finishing (Jha and Jain, 2004)**

Sharma et al. developed an Ultrasonic Assisted Abrasive Flow Machining (UAAFM) process in which workpiece is subjected to ultrasonic vibration perpendicular to the media flow direction. Fig. 5. shows the schematic diagram of UAAFM process. Das et al. proposed Rotational Magnetorheological Abrasive Flow Finishing (RMRAFF) process to enhance the surface finish of MRAFF process. In this process, a rotation and reciprocating motion is provided

to the abrasive medium by a rotating magnetic field and hydraulic unit as shown in Fig. 6. Smooth and mirror-like surfaces are observed in both stainless steel and brass workpieces.

**Fig. 5. Schematic diagram of UAAFMM (Skarma et. al 2015)**

**Fig. 6. Schematic diagram of R-MRAFF**

Shankar et al. (Sankar, Mondal and Rajkumar, 2009) proposed a concept of rotating medium along the axis to enhance the surface finish and material removal rate. This process is known as Drill bit guided abrasive flow finishing (DBG-AFF) process as shown in figure 7.

**Fig. 7. Schematic diagram of DBG-AFF (Sankar, Mondal and Rajkumar, 2009)**

Shankar et al. (Sankar, Jain and Ramkumar, 2009) developed a model of Rotational Abrasive flow finishing (R-AFF) process. In this method the component to be finished is rotated at high speed in order to enhance the surface quality. Figure 8 shows the schematic diagram of R-AFF process.

**Fig. 8. Schematic diagram of R-AFF**

#### 4. DEVELOPMENT IN ABRASIVE MEDIA

Abrasive media is main constituent of the AFM process. The medium consists of viscoelastic polymer reinforced with the abrasive particles. In this viscoelastic polymer acts as a carrier medium and abrasive particles acts as a cutting

tool which removes the material from the workpiece. The commonly used polymer media are polyborosiloxane and silicone rubber and commonly used abrasives are silicon carbide, aluminum oxide, boron carbide and polycrystalline diamond (Santosh Kumar et al.) Researchers have tried to develop different alternatives to abrasive media which are highlighted in table below.

**TABLE 2. Different types Abrasive media**

Sr. No	Authors	Abrasives & its concentration	Polymer carrier	Results
1	Sankar et al. [18]	SiC	Styrene-Butadiene Rubber	MRR and surface finish is affected by Rheological properties of media
2	Wang et al. [19]	SiC with different mesh size (50%)	Silicon Rubber Silicon Rubber with additives	High quality finish was observed with silicon rubber with additives.
3	Kar et al. [20]	SiC with different mesh size (68%)	Natural Rubber Butyl Rubber	Butyl rubber showed better performance than Natural Rubber. Polymer media also affects the surface finish.

## 5. ADVANCED APPLICATIONS OF ABRASIVE FLOW MACHINING

Abrasive flow machining has wide range of applications. In case of cylinder block of engine, surfaces with low sliding friction and high wear resistance are present. Also precision mechanical components finished with mass finishing provide a low torque performance and a long service life. Silicon wafers or manifolds of engine also require high surface fineness; such components have to be finished on advanced options like abrasive flow machining.

**Fig. 9. Engine Cylinder Block**

**Fig. 10. Manifolds**

G. Venkatesh et al. (G. Venkatesh et al, 2015) has applied Ultrasonic assisted AFM process for finishing bevel gears made of EN8 steel. An analysis of the process has been presented with suitable illustrations. A finite element simulation of the behaviour of the medium during finishing of bevel gears using the UAAFM process has been presented. A 3D model was constructed to simulate the flow of medium through the outer wall of the gear tooth surface using computational fluid dynamics (CFD) approach. The velocity, pressure and temperature values along the length of the workpiece were computed for both UAAFM and the conventional AFM processes. Further, the effectiveness of the process was investigated through experimental trials by conducting a comparison study between classical AFM and UAAFM. Ultrasonic frequency, extrusion pressure, processing time and the media flow rate were considered as the input variables while improvements in surface finish and material removal were considered as the monitored outputs. Results concluded that improvements in surface roughness and material removal are significantly higher than those obtained with conventional abrasive flow machining. The work has also inferred that applied high frequency (ultrasonic) vibration to the workpiece has the maximum influence on the process responses among the variables considered.

The Navier–Stokes equation (Eq. (1)) was used for fluid flow simulation in order to define the fluid flow characteristics.

$$\rho \left( \frac{\partial u}{\partial t} + u \cdot \nabla u \right) = -\nabla p + \nabla \cdot T + f_i \quad (i)$$

where  $u$  is the velocity vector, m/s,  $\rho$  is the fluid density, kg/m³,  $p$  is the pressure, Pa,  $T$  is the component of total stress tensor, N/m²,  $f_i$  is the body forces (per unit volume) acting on the fluid, N/m³, and  $\nabla$  is the vector differential operator.

Milk deposits are the serious technical and economic problem for the dairy industry. Ikko Ihara et al. (Ikko Ihara

et.al. 2016) used Magnetic abrasive finishing process to produce highly finished inner surfaces of stainless steel tubes to compare to tubes with conventional inner surfaces. Deposition and cleaning tests were carried out using an experimental loop including the stainless steel tubes with different surface roughness profiles. Data showed that the smoothly finished inner surface ( $R_a = 0.037 \mu\text{m}$ ) of stainless steel tubes prepared by MAF significantly improved the cleanability of milk residues. The results indicated that the cleanability of non-protein components of milk residue is affected by surface roughness.

## 6. CONCLUSION

Abrasive flow machining uses visco-elastic polymer and abrasive particles mixed in a definite proportion. In this paper attempt has been made to review the published technical papers on AFM process. The paper comprises of three different sections- Advanced setups of AFM process, Different combinations of Abrasive media and the applications of advanced setups in field of Agriculture, Engineering and biomedical applications. From the above discussed literatures following things can be concluded.

- Following advanced experimental setups developed by the researchers are highlighted in this paper. Magneto Abrasive Flow Machining (MAFM), Hybrid electrochemical and centrifugal force assisted AFM process, Magneto rheological abrasive flow finishing process, Drill Bit Guided-Abrasive Flow Finishing (DBG-AFF); Rotational-Abrasive Flow Finishing (R-AFF) and Ultrasonic Assisted Abrasive Flow Machining (UAAFM) which can improve the surface finish of the machine components.
- Different abrasive media with various mesh size and polymer carrier are introduced. It is concluded that polymer carrier, abrasive media with its concentration affects the surface finish of material. Thus such different combinations of abrasive media and polymer carrier can be used rather than traditional abrasives like silicon carbide, aluminum oxide in order to get better surface finish.
- At the end of paper, some typical examples like machining of bevel gears and internal surface finishing of milk containers in dairy industry are discussed. Thus advance develop setups of AFM can be applied in various fields of engineering.

# Casting Yield Improvement using Modeling and Simulation Technique

Amar S. Yekane

Department of Mechanical Engineering  
Finolex Academy of Management and Technology, Ratnagiri, Maharashtra, India

---

**Abstract:** Yield is the ability of a foundry to manufacture acceptable casting in a cast effective manner. Improving yield offers many financial benefits to the foundry. Along with direct cost control, high yield is also associated with better quality and process control. By using casting simulation, an optimum gating system can be designed to improve the yield of the casting. This paper presents work on analysis of a real world industrial casting for yield improvement. A commercially available software AutoCast has been employed for this purpose. Further, design of experiments (DoE) technique has been used to predict the significant factors and its effect on casting yield and rejection. The modifications suggested in this paper resulted in 0.42% improvement in yield at box level. At the overall foundry level, 2.72% improvement in yield has been realized.

**Keywords:** Casting simulation. Gating design, Yield, Quality

---

## 1. INTRODUCTION

Foundry industry is one of the oldest manufacturing industries. In the current scenario of global manufacturing, cost effectiveness and quality are crucial factors for survival of foundries. There is continuous pressure on foundries to supply castings at lower prices, shorter lead times with assured quality than ever before. The profit of a foundry is greatly influenced by the casting yield, which in turn is defined as the total weight of good casting expressed as a percentage of the total weight of metallic material melted to produce them. Yield is a measure of foundry's ability to manufacture saleable castings in cost effective manner achieving the required quality. Achieving a balance between yield, defect free casting and manufacturing cost is always a challenge for foundries. Involvement of several parameters related to casting design (i.e. size, shape complexity, weight, and section thickness), material and process (molding material, feeding and gating methods, feed aids etc.) makes it a challenging problem. Due to complexity of the process, it is challenging to alleviate the defects (such as shrinkage porosity, blow holes, incomplete filling). Proper gating/feeding system design is critical to eliminate these defects as well as improve the casting yield. The quality of casting can be predicted by casting simulation, and if any defects are observed can be corrected by suitable modification in the gating and feeding system. Many researchers reported that, about 90% of the defects in castings are due to improper design of gating and feeding system, and only 10% due to manufacturing problems. Thus, casting solidification simulation enables predicting and preventing potential problems in advance to achieve high yield at the desired quality level, and helps to develop the casting process in an optimal manner.

In the literature, various techniques such as design of experiments and casting simulation have been reported for defect analysis. A large number of experimental investigations linking gating parameters with casting quality have been carried out by researchers and foundry engineers over the past few decades. Several commercial tools (such as AutoCast, Z Cast etc.) have been developed to perform the casting simulation. It has been reported that casting yield increased from 56% to 72% eliminating the defects. Computer simulation minimizes the failure rate to a huge extent compared to manual trials. The simulations were used to predict the temperature distributions and solidification sequences in the casting to optimize the casting conditions. Casting simulation has become a powerful tool to visualize mould filling, solidification and cooling, and to predict the location of internal defects such as shrinkage porosity, sand inclusions, and cold shuts. Iron foundries use these varieties of methods and software for design of feeding systems. The application of casting simulation software in the foundries not only minimizes the wastages of resources required for final castings, but also improves / enhances the quality and yield of castings, which implies higher value addition and lower production cost.

In the current work, the simulation and experimental investigations are carried out on real life industrial casting of 'Case Transmission' to improve the yield. AutoCast one of the commercially available simulation software has been used for this purpose because of its availability and proven ability. The AutoCast comprises a suite of nine programs to perform various tasks associated with casting design. Each program comprises a set of modules for design, solid modeling, simulation, analysis and improvement. As a part of this study, existing process of manufacturing casting has been studied and few modifications have been done in

gating design for improving casting yield and quality. The influence of key process parameters on yield and quality (rejections) have been studied using Taguchi Techniques. Further, new gating system is proposed. The results of simulation have been validated through shop floor trials. In the next section, importance of yield has been explained. In the subsequent sections, overall methodology, results of experimentation and modifications done are explained in details.

## 2. IMPORTANCE OF YIELD

As mentioned earlier, yield is defined as the total weight of good, saleable castings expressed as a percentage of the total weight of metallic materials melted to produce them. It can be represented as,

$$Yield = \frac{\text{Total weight of good castings}}{\text{Total weight of metal melted}} \times 100$$

Actual yield of a foundry is always less than 100% because weight of the metal melted always exceeds that of the good quality castings dispatched. Other than material saving, improvement in yield also helps to reduce the costs associated with melting the metal (energy cost).

## 3. METHODOLOGY

The overall methodology for the current work is depicted in figure 1. The main steps in the current approach are:

1. Study the existing process and method
2. Simulation for existing method
3. Design of Experiments (DoE) and shop floor trials
4. Design modifications and shop floor validation

These steps are explained in next subsections.

STEP 1	STEP 2	STEP 3	STEP 4
<u>Study of existing process</u>	<u>Simulation for existing method</u>	<u>DoE and shop floor trials</u>	<u>Design modifications and shop floor validation</u>
-Part model     -Material     -Process parameters     -Methods design     -Existing defects	-Parting lines     -Cores     -Feeders     -Feedaids     -Gating system     -Mould cavity layout	-Selection of critical parameters     -Analysis of results     -Shop floor trials	-Modification in existing design     -Simulation and analysis of modified design (step 2 is repeated)     -Shop floor verification

**Fig. 1. Overall methodology**

### 3.1 Study of existing process

As mentioned earlier, Case Transmission Casting has been selected for yield improvement (please refer figure 2). The data pertaining to manufacturing the casting has been collected from the shop floor. Main parameters related to casting manufacturing are shown in table 1.

**Fig. 2. Case Transmission Casting**

**TABLE 1: Component and process details**

<b>Grade of Metal : FG 220</b>	<b>Unit weight of casting: 61 kg</b>
Height of casting (C): 375 mm	Sand material: Green sand
Pouring temperature (T _p ): 1430 °C	Feeding time: 15 seconds
Liquidus temperature: 1250 °C	Solidus temperature: 1154 °C
Density of metal: 7200 kg/m ³	Total weight of casting in mould box: 61*2 = 122
Total dimensions of the mould box: 1200 mm x 800 mm x 725 mm	Type of gating system used: Hybrid Gating system
Shape of mould box: Rectangular	Mould layout : 2 castings per mould

The feeding and gating design for existing method have also been studied and analysed in detail. The results of simulation for existing method are discussed in brief in the next subsection.

### 3.2 Simulation results for existing method

With the help of relevant information, the simulation trial was taken in order to analyse the defect for the existing gating system. In the existing system, a central sprue was used to feed both the cavities of two cavity mould. The pouring was done through a sprue which was connected to the runner. The runner was connected to mould by means of ingates (figure 3(b)). The results of simulation, especially for the defects related to solidification and blow holes are shown in figure 3(c) and 3(d).

(a)

(b)

(c)

(d)

**Fig. 3. Simulation results for existing system: (a) Massive section shows chances of hot spot (b) Hot spot absorbed in sprue cup (c) Shrinkage porosity absorbed in sprue cup (d) Prediction of blow holes**

The simulation result shows that, the hot spot is absorbed in the sprue cup and there is almost no shrinkage porosity in casting. However, blow holes have been predicted at the corner of castings (encircled in figure 4d). The results were verified with the real castings manufactured by the foundry. It was verified that, indeed there was a significant rejection (5-8%) because of blow holes in the foundry at the predicted location. The box yield with the existing design was 81.33%.

Further investigations were performed to improve the box yield and reduce the defects related to blow holes.

### 3.3 Modification in gating design and results:

Several experiments were conducted to study the effect of important parameters (pouring temperature, moisture content, compactibility and gating ratio) on yield and quality. The principles of Taguchi method were applied for conducting these experiments. L8 array has been used for experimentation. Based on discussions with domain experts, various levels of these parameters have been selected. These levels are shown in table 2. For each of the simulation run, the value of box yield, and potential defect have been predicted through software. In addition, shop floor trials were taken to determine rejections pertaining to these modifications. The data collected from these experiments is shown in table 3. Collected data have been analyzed using Taguchi method. Taguchi method uses signal to noise ratio in order to convert the trial result data into a value for the optimum setting analysis. The signal to noise ratio (SN) ratio main effect plots for various response variables are shown in figure 4. Minitab16 software has been used to study the influence of various parameters on yield and rejections.

**TABLE 2: Factors and Levels**

Process parameter	Level 1	Level 2
Moisture content (%)	3.2-3.5	3.5-3.8
Compactibility	38-40	40-42
Pouring temperature(°C)	1415-1425	1435-1445
Gating ratio	1:2:1.5	1:1.6:0.8

**TABLE 3: Standard L8 array for % rejection and yield along with S/N ratio values**

Moisture	Compactibility	Pouring temperature	Gating ratio	% Rejection	Yield	SNRA1	SNRA2
1	1	1	1	7.95	72.61	-18.0073	37.2199
1	1	2	2	1.13	81.33	-1.0616	38.2050
1	2	1	2	2.27	81.33	-7.1205	38.2050
1	2	2	1	6.81	72.61	-16.6629	37.2199
2	1	1	2	3.40	81.33	-10.6296	38.2050
2	1	2	1	5.68	72.61	-15.0870	37.2199
2	2	1	1	9.09	72.61	-19.1713	37.2199
2	2	2	2	4.54	81.33	-13.1411	38.2050

(a)

(b)

**Fig4: (a) S/N Main effects plot for % rejection (b) S/N Main effects plot for box yield**

As evident from the analysis, within the selected range, the most influencing parameter on rejection is the gating ratio, which accounts for (76.20%) of the total effect. All other parameters such as moisture content, compactibility and pouring temperature are less significant parameters. From SN ratio plots, it is clear that percentage rejection and box yield are minimum and maximum respectively at second level (1:1.6:0.8) of gating ratio, first level (3.2-3.5) of moisture content, first level (38-40) of compactibility and second level (1435-1445) of pouring temperature. Based on the above analysis, simulation results, inputs from domain

experts and some practical constraints from foundry, following improvement were proposed for yield and quality improvement:

- Runner bar modification: The height of the runner bar is reduced by 6mm as shown in figure 5. This resulted into 0.74 kg mass reduction.
- Addition of vent (encircled in figure 6(a)) for escaping the gases and prevent the blow holes (encircled in figure 6(d)).

The simulation study was carried out with these improvements. The results of this study are shown in figure 6. As evident from the figure, with proposed modifications the defects related to blow holes have been eliminated. In addition, decrease in runner bar size resulted in 0.42% improvement in box yield i.e. 0.74 kg saving of material.

With this method, trials were performed in shop floor and realized that defects pertaining to blow holes have been reduced to 1.5%. This reduction in defects also contributed to improvement in overall foundry yield. Thus, 2.72 % overall yield improvement has been observed in the foundry.

#### 4. CONCLUSIONS

In this paper, an application of a simulation software program for mold filling, solidification analysis and yield improvement has been presented. The simulation program has been used to identify critical locations, filling pattern and solidification related problem areas in the casting. Based on the analysis of simulation and experimental results modifications in the gating system have been performed. These modifications resulted in 0.42 % improvement in yield at box level and 2.72% improvement in yield at overall foundry level. The higher improvement in yield at foundry level was realized because of reduction in rejection percentage. A significant benefits and savings have been realized by the foundry. These include savings in the costs associated with in metal, time, labor and energy. Further, experimental investigations were carried out to study the influence of various parameters on yield and quality, and analysis was done using Taguchi techniques. For the selected parameter levels, it was realized that percentage rejection and box yield are minimum and maximum at second level (1:1.6:0.8) of gating ratio, first level (3.2-3.5) of moisture content, first level (38-40) of compactibility and second level (1435-1445) of pouring temperature.

**Acknowledgment:** The authors would like to express appreciation for the support from Ghatge Patil Industries. Authors appreciate the great help from Mr. Milind Bhave (Vice President, Foundry Division, Ghatge Patil Industries) for his professional suggestions on research work. My deepest gratitude goes to Mr. Sanjay Mali of Genesis Technocrats.

# A Comprehensive Review of Optimisation Techniques Employed in Conventional Drilling Operation

Jamil Ahmad, Tarun Verma, Manoj Kumar Sinha

Department of Mechanical Engineering, National Institute of Technology, Delhi, India

---

**Abstract:** Drilling is one of the most versatile conventional machining processes which is influenced by parameters such as spindle speed, feed rate, drilling depth, point angle, drill bit diameter, friction contact area ratio and tool type. A substantial number of research articles have been found dealing with the improvement in drilling performance of few widely used materials. The present review article presents a comprehensive review in deciding the optimised parameters through different optimisation techniques. The drilling of important and widely used engineering materials such as alloys, composites and ceramics has been addressed. Such studies are mainly focused on the different aspects of the drilling responses like surface roughness, thrust force, tool wear and associated physical phenomena. Such study can serve as a platform for the researchers in deciding the better-suited optimisation tool in the drilling of new and advanced materials.

**Keywords:** Optimisation techniques, Taguchi method, Drilling review, RSM.

## 1. INTRODUCTION

The present scenario of increased customer awareness as well as the demand for the quality products leads to the rapid growth in huge competition amongst the producers globally. It resulted in the optimum usage of the resources and optimisation of the machining parameters. Nowadays, many conventional and non-conventional machining processes are used in the manufacturing of quality products using different materials. Still, use of the conventional machining operations covers a substantial portion of the total manufacturing processes. Out of the widely used conventional operations, drilling is the most versatile conventional machining operation used in machining of important engineering materials. Drilling operation covers around 40% of all conventional machining processes (Ku et al., 2010). In the present scenario, achieving better quality to improve the performance of the product is the basic necessity of every industry. However, many production industries encounter certain challenges such as dimensional as well as geometrical tolerances, better surface finish, high production rate and reduced tool wear. Increase in the metal removal rates leads to high productivity in machining operations. It is very difficult to balance the high metal removal rate and tight tolerance limits (Sheth et al., 2016). Therefore, optimisation of the drilling parameters becomes essential to improve the product quality and to reduce the overall cost of the product.

Drilling is a conventional machining operation of producing a cylindrical hole in a solid workpiece using a revolving tool called drill bit. The drilling of circular holes is one of the most common operations among all the machining processes and is more complex than other metal removal processes due to the access problem. The decline in

performance level under severe drilling conditions is another important difficulty associated with the drilling tools. The drills are buried in the workpiece, which obstructs the removal of chips away from the work zone (Huang and Lin, 2004). The quality of drilling operation is mainly influenced by the input parameter like feed rate, spindle speed, cutting speed, point angle of the drill bit, drill type and diameter of the drill bit. Since there are many parameters which affect the quality of drilling operation, it became necessary to use optimised drilling input parameters to get the improved quality of drilling products.

The present study presents a critical review of the important research articles dealing with the application of optimisation techniques in the drilling operation. Although the research in optimisation techniques is almost six decades old however the use of the optimisation techniques in drilling operation has been started 2004 onwards. The optimization of drilling parameter on different engineering material like aluminum alloy 6061 (Huang and Lin, 2004), LM25-based aluminum alloy reinforced with bonded silicon carbide of size 25  $\mu\text{m}$  (Haq et al., 2007), glass fiber reinforced plastic (Kilickap, 2010a), coir fibre-reinforced composites and other natural fibre-reinforced Composites (Jayabal and Natrajan, 2010), SUS 304 stainless steel (Ku et al., 2010), carbon fibre-reinforced epoxy composites (Shahrajabian and Farahnakian, 2013), copper (Kannan et al., 2014), Al/SiC/Al₂O₃ hybrid composite (Adalarasan and Santhanakumar, 2015), sandwich composite (steel and jute as reinforcements and polyester as the matrix material) (Vinayagamoorthy, 2016), wrought cast steel grade B (Sheth et al., 2016) have been performed using different optimization techniques for improving the quality of drilling operation. These articles also describe the in-built

drilling challenges with their possible solution during drilling of various materials.

The present extensive review has been performed in the framework of optimisation of input parameters of drilling for different materials to get the improved quality of drilled products. Such optimised conditions also help in reducing the machining time and related input attributes which eventually culminate in minimisation of the process costs. It can also be helpful in selection and alter the input drilling parameters depending upon the level of the quality products required. A brief explanation of different optimisation techniques used in drilling operation has been presented in the upcoming section. The main of this review article is to present a comparison between the various optimisation techniques purpose used and explore the better-suited optimisation technique for customising the drilling operation.

## 2. LITERATURE REVIEW

The engineering optimisation is the process of identifying the best combination of the input parameters for the customised output responses for a given material under prescribed working environment. Traditionally, the optimisation is often done manually which is an exhaustive and time-consuming process. The manual approach was time-consuming, and the searching ability of it is limited which often lead to sub-optimal solutions. In recent decades, some advanced optimisation approaches have been developed which offers more accurate results in less time than manual optimisation approaches. Normally, before the application of optimisation technique, corresponding mathematical modelling is developed for the output responses by using input parameters of the specific process. Response surface methodology (RSM), Taguchi method, Genetic algorithm, Particle swarm optimisation (PSO) and statistical-based multi-gene genetic programming are some of the extensively used optimisation techniques applied in customising the drilling operations.

### 2.1 Taguchi method

Taguchi method is one of the simplest and effective approaches for parametric design and experimental planning (Fisher, 1925). This method works by evaluating the signal and noise ratio for a set of experimental data for a specific manufacturing process. The term 'signal (S)' represents the desired value for the output characteristics whereas the term 'noise (N)' represents standard deviation for the output characteristic. Therefore, the signal to noise ratio (S/N ratio) is the ratio of the mean to the standard deviation for a particular output variable concerning. There are three types of S/N ratio depends on the type of characteristics; lower-the-better, higher-the-better and nominal-the-better. The selection of S/N ratio primarily depends on the nature of the response variable (Nian et al., 1999). Huang and Lin (2004) have used

Taguchi method based on Grey rational analysis for optimising the performance characteristics such as tool life, mean surface roughness and burr height in the drilling of Aluminum alloy 6061. They used a drill bit with coated deposition of TiN, TiAlN and CrN, spindle speed and feed rate as input parameters and had achieved better performance characteristics. Based on their study, they found that the multiple parameter characteristics are affected mostly by coated deposition. For optimal points of drilling parameter for tool life is CrN coated drill bit, spindle speed 2000 rpm, and feed rate 0.1 mm/rev. Haq et al. (2007) have used Taguchi method based on Grey relational analysis for optimising the performance characteristics such as cutting force, surface roughness and torque in the drilling of LM25-based aluminium alloy reinforced with bonded silicon carbide of size 25  $\mu\text{m}$ . They have used cutting speed, feed rate and point angle as input parameters. Kilickap (2010a) has used Taguchi method for optimisation of delamination in drilling of Glass fibre reinforced plastic. He has used cutting speed, feed rate and point angle as input parameters. He has found that Feed rate and cutting speed is the most influential parameter on the delamination. He concludes that lower cutting speed and feed rate is giving the better result of the delamination. Kilickap (2010b) has used Taguchi method based on RSM for optimisation of the burr height and surface roughness in the drilling of Al-7075. He has used cutting speed, feed rate and point angle as input parameters. RSM and Taguchi's method has been used for optimisation. Based on his study, he found Taguchi method as the most suitable technique to predict the burr height and the surface roughness. He found the lowest burr height and surface roughness occurred at a low feed rate, low cutting speed and high point angle. Ku et al. (2010) have used Taguchi method for optimisation of surface roughness (SR) and bushing length (BL) in drilling of SUS 304 stainless steel. They have used friction angle (FA), friction contact area ratio (FCAR), feed rate (FR) and spindle speed (SS) as input parameters. They have found that the bushing length of the drilled hole is nearly three times longer than the plate thickness under the optimal friction drilling condition, the friction angle and the spindle speed are significantly affecting surface roughness in thermal friction drilling. The optimal machining parameters regarding FA, FCAR, FR and SS for surface roughness in the drilling of SUS 304 stainless steel were 30°, 50%, 100 mm/min and 3600 rpm respectively. The friction contact area ratio is the only significant parameter for bushing length in thermal friction drilling as reported by them. Taskesen and Kutukde (2013) have used Taguchi method for optimisation of tool wear, and diametrical error in the drilling of B₄C reinforced Al-alloy. They have used spindle speed, feed rate and content of B₄C as input parameters. They have found that the tool wear increases with particle mass fraction and decreases with feed rate, the dimensional accuracy is negatively affected by the tool wear. They also found and reported the optimum values of

spindle speed, feed rate and content of B₄C regarding the minimal value of tool wear and diametrical error. Neseli (2014) has used Taguchi method for optimisation of thrust force and torque in the drilling of AISI 1040 steel. He has used cutting speed, feed rate and helix angle as input parameters. Based on his studies, feed rate and cutting speed were established as the dominant factor for thrust force and torque respectively. He found that the optimum values of input parameters are cutting speed 28 m/min, the feed rate 0.1 mm/rev and helix angle 30° which gives optimum thrust force of 1030 N and torque of 16.82 Nm. Siddiquee et al. (2014) have used Taguchi method in forminimising surface roughness in the drilling of AISI 321 austenitic steel using input parameters such as cutting fluid, spindle speed, feed rate and hole-depth. They have found that the surface roughness is mainly influenced by spindle speed, feed rate, cutting fluid and hole-depth and the surface roughness is improved by 131% from initial cutting parameter to the optimal cutting parameters. Minimum value of surface roughness (3.14 µm) was observed at spindle speed: 500 rpm, feed rate: 0.04 mm/s and hole-depth: 25 mm with the application of cutting fluid. Prasanna et al. (2014) have used Taguchi method based on gray rational analysis for optimisation of thrust force, overcut, circularity and taper in drilling of Ti-6Al-4V plate of 0.4 mm thickness. They have used spindle speed, feed rate and air pressure as input parameters. According to them spindle speed and air pressure comes out to be most significant parameters for the reduction of thrust force, overcut, circularity and taper angle. Abhishek et al. (2015) have used an integrated multi-response optimization philosophy by combining principal component analysis (PCA), fuzzy inference system (FIS) and Taguchi method for the minimization of thrust force, torque and entry/exit delamination factor in the drilling of carbon fiber-reinforced plastics. They have used spindle speed, feed rate and hole-depth as input parameters. They found that the highest drill speed, lowest feed and drill diameter is producing minimum torque, minimum thrust, and minimum delamination factor both at entry as well as exit. For minimum value of thrust force, torque and entry/exit delamination factor, the optimum value of input parameter are spindle speed 2800 rpm, feed rate 50 mm/min and hole-depth 6 mm. Kamboj et al. (2015) have used Taguchi method for minimizing the burr height and hole diameter error while drilling of AL6063/15%/SiC composites by using input parameters such as cutting speed, feed rate, step angle and cutting environment. According to them, the drilling-tool geometry plays an important role in the drilling of aluminium matrix composites. They found that feed rate and step angle have significant effect on burr height and hole diameter error, feed rate and step angle affect directly on burr height and hole diameter error while cutting speed effect inversely on burr height and hole diameter error. Balaji et al. (2016) have used Taguchi method for the optimisation of acceleration of drill bit vibration and

surface roughness in drilling of AISI 304 stainless steel for evaluation of tool life. They have used helix angle, feed rate and spindle speed as input parameters. They have observed increase in vibration of drill bit with the progression of the tool wear. According to them helix angle have significant effect on surface roughness and acceleration of drill vibration velocity with contribution of 78.22% and 50.02% respectively.

Akinciog˘ luet al. (2017) have used Taguchi method for optimising the surface roughness and thrust force in drilling of AISI D2 steel by using cryo-treated carbide drills. The input parameter was feed rate and cutting speed. They found that the feed rate is amost influential factor, affecting both surface roughnesses (66.97%) and thrust force (80.07%), the cryo-treated and tempered drills provide the lowest values of surface roughness and thrust force in comparison with the untreated and cryo-treated drills because of their improved wear resistance. They found the optimum values of input parameter were feed rate 0.063 mm/rev and cutting speed 60 m/min. AY et al. (2017) have used Taguchi method based on grey rational analysis for optimisation of surface roughness and cutting force in drilling of a hybrid Al/SiC/Gr metal matrix composites. They have used rate of graphite, feed rate and spindle speed as input parameters. They have taken Al/20%SiC/5%Gr, Al/20%SiC/7.5%Gr and Al/20%SiC/10%Gr as metal matrix composite composition. Based on their study they found that rate of graphite (10%), spindle speed (4500 rpm) and feed (0.1 mm/rev) were significant parameters for cutting force and surface roughness. Can and Ünüvar (2017) have used Taguchi method for the optimisation of surface roughness, thrust force and push out and peel up delamination behaviour in the drilling of glass fibre reinforced sheet mould compound composites. They have used feed rate, cutting speed and drill bit angle as input parameters. According to them, the drill bit angle was amost influential parameter for reduction of thrust force, delamination and surface roughness.

## 2.2 Genetic Algorithm

Genetic algorithm (GA) is a class of stochastic research methods that use techniques inspired by evolutionary biologies such as inheritance, mutation, selection and crossover. GA operates on a population of potential solutions applying the principle of survival of the fittest to produce better and better approximations to a solution. A major advantage of GA over other algorithms is that they need a type of primary guess about the solution, which is significantly effective on the result. GA needs a search range, which is presented according to the initial information of the physical properties. The evolution starts from a population of completely random individuals and occurs in generations. In each generation, the fitness of the whole population has been evaluated; multiple individuals are stochastically selected from the current population, and

mutated to form a new population. The new population is then used in the next iteration of the algorithm. This type of search does not fall into the optimum local values (Shahrajabian and Farahnakian, 2013).

Jayabal and Natrajan (2010) have used Nelder-mead and GA for optimisation of tool wear, thrust force and torque in the drilling of coir fibre-reinforced composites and other natural fibre-reinforced composites. They have used drill bit diameter, spindle speed and feed rate as input parameters. They have found that the accuracy of drill holes is increased when the tool is in good condition. They obtained minimum thrust force occurs at lower drill bit diameter, higher speed, and lower feed rate for coir fibre reinforced composites. For minimum tool wear the optimum value of input parameter is drill bit diameter is 6 mm, spindle speed is 600 rpm and feed rate 0.3 mm/rev. Kilickap et al. (2010c) have developed RSM based surface roughness mathematical model and have used GA optimisation in the drilling of AISI 1045. They have used cutting speed, feed rate and cutting environment as input parameters. They have found that cutting speed, feed rate and cutting environment were dominating parameters that contribute in minimising surface roughness. Kumar and Paulraj (2011) have used GA for optimisation of machining accuracy by minimising workpiece deformation in the drilling of Al-6061 and Al-7075. For this, support locations were optimized for minimum workpiece deflections, and with the help of optimised clamping forces, the highest locating accuracy was achieved. Shahrajabian and Farahnakian (2013) have developed RSM based mathematical model and have used GA for optimisation in the drilling of Carbon fibre-reinforced epoxy Composites. They have used spindle speed, feed and point angle as input parameters. They obtained minimum thrust force at tool point angle  $60^\circ$ , the minimum surface roughness when tool point angle  $140^\circ$  and the minimum delamination achieved at spindle speed 4000 rpm, tool point angle  $100^\circ$ . They found that feed rate is the most significant factor for thrust force, delamination and surface roughness. Kannan et al. (2014) have used GA and PSO in association with Artificial Neural Network modelling for optimisation of ovality, thrust force, surface roughness and machining time in the drilling of copper material. They have used spindle speed and feed rate as input parameters. They have found that the quality and production rate of drilling operation are significantly affected by spindle speed and feed rate. They conclude that compared with PSO, GA is giving better results for thrust force and surface roughness, compared with GA, PSO is giving better results for machining time and ovality. Shunmugesh and Panneerselvam (2016) have used Hybrid Particle swarm optimisation gravitational search algorithm (PSOGSA) and GA in the drilling of carbon fibre reinforced polymer for optimisation of thrust force, torque and surface roughness. They have used cutting speed, feed rate and drill bit type as input parameters. They have found that Artificial

Neural Network approach is effective in predicting the minimum value of thrust force, torque and surface roughness compared to the experimental values. The proposed hybrid algorithm, PSOGSA converges to the optimal solution with a lesser number of iterations compared to the GA.

### ***2.3 Response surface methodology based desirability function approach***

RSM is a collection of statistical and mathematical techniques useful for developing, improving and optimising processes. It uses quantitative data from appropriate experimental designs to determine and simultaneously solve multivariate equations graphically represented as response surfaces (Khuri and Mukhopadhyay, 2010). In desirability-based approach, different solutions are obtained, and the solution with high desirability is preferred. Rajamohan and Palanikumar (2013) have used RSM based desirability function approach for optimisation of burr height, thrust force and surface roughness in the drilling of Al 356-aluminium alloy reinforced with silicon carbide of size 25 microns and mica of an average size of 45 microns. They have used spindle speed, feed rate and wt% of SiC as input parameters. They found that feed rate and speed are the dominating parameters that contribute to improving surface quality, reducing the thrust force and burr height. They obtained for the optimum value of burr height, thrust force and surface roughness with the optimised value spindle speed, feed rate and wt% of SiC as 1855 rpm, 50 mm/min and 15% respectively.

Meralet al. (2015) have used RSM based desirability function approach for optimisation of surface roughness, dimensional accuracy, circular deviation and axial misalignment between inlet and outlet of holes in the drilling of AISI 1050 Steel. They have used drill diameter, cutting speed, feed rate and tool type as input parameters. They concluded that the coated tools give better surface quality at high cutting speed and medium feed rate. However, good dimensional accuracy was achieved from lower cutting speed, medium feed rate and using the coated tool. They conclude that geometric precision of the holes is significantly affected by the cutting speed and feed rate, axial misalignment increased with decreasing drill diameter and decreased using the coated tool. For uncoated and coated tools, the most significant parameter on surface roughness is drill diameter whereas dimensional accuracy, circular as well as cylindrical deviations are significantly affected by cutting speed. Geier and Szalay (2017) have used RSM for optimisation of axial cutting force, delamination effect and surface roughness in drilling of uni-directional carbon fibre-reinforced polymers. They have used cutting speed, feed rate and screw pitch of the feeding helix as input parameters. They found the optimum value of cutting speed, feed rate and screw pitch of the feeding helix are 50 m/min, 0.049 mm/rev and 3 mm respectively.

## 2.4 Other techniques

Garg et al. (2014) have used statistical-based multi-gene genetic programming approach to optimise the burr height and average surface roughness. They took AISI 316 stainless steel as work material in drilling process. They have used cutting speed, feed rate, point angle, drill diameter and lip clearance angle as input parameters. Based on their finding, they opined that the feed rate, clearance angle and drill diameter are the most influencing parameters on burr height of the drilled component. Vinayagamoorthy (2016) has used Box-Behnken technique for optimisation of thrust force, surface roughness and damage at the entrance surface in the drilling of the sandwich composite which has steel and jute as reinforcements and polyester as the matrix material. According to him, spindle feed, point angle and tool diameter were the dominants affecting thrust force where as spindle speed and tool diameter were influencing the hole-wall roughness. Spindle speed, spindle feed and point angle have a major dominance on the profile damage of the drilled inner surface. He concluded for the output responses, the optimum value of input parameter are spindle speed 1070 rpm, feedrate 0.1 mm/rev, point angle 90° and tool diameter 8 mm which is very close to the obtained experimental result. Sheth et al. (2016) had used multi-objective optimisation based on Grey relational analysis to optimise cylindricity and perpendicularity of hole while drilling wrought cast steel grade B material. They have used spindle speed, feed rate and depth of cut as input parameters. They found that spindle speed and feed were significant parameters for cylindricity and perpendicularity. Minimal cylindricity is achieved at lower spindle speed, lower feed and moderate depth of cut, Minimal perpendicularity is achieved at higher spindle speed, lower feed and lower depth of cut.

## 3. SUMMARY OF THE REVIEW

The present review article summarises the application of different optimisation techniques adopted in the analysis of drilling parameters. The article also talks about the optimised drilling factors for different drilling responses. It also covers the comparisons between the results obtained from the different techniques for same drilling input parameter. From this review, it is evidently indicated that use of optimisation techniques results in achieving the substantial improvement in the surface integrity of the drilled products and which eventually results in a reduction in total cost of machining by selecting an optimal set of design and the operating parameters for the drilling operation. The optimisation techniques used the range of operating and design parameters to the objective of study, therefore by selecting optimum parameters set of corresponding optimum results can be obtained. From this article, it is observed that the comparison of the various optimisation techniques either used the single or in combination

give the close values as compared to the experimental findings.

# Process Failure Mode and Effect Analysis of Hot Rolled Pickled Steel Strip

A.R. Pawar, S.B.Chikalthankar, Y. R. Tambatkar

Department of Mechanical Engineering  
Government College of Engineering, Aurangabad, Maharashtra, India

---

**Abstract:** The Process FMEA (PFMEA) Technique is used at keshav Metal pvt. Ltd. Waluj, (MIDC), Aurangabad (M.S.) for identifying potential Failures of Hot Rolled pickled Steel Strip. The study present an effective tool for solving the problem of Manufacturing Industry by executing process FMEA with proposed process control practices. This study help to identify and eliminate current and potential problems from a manufacturing process of Hot Rolled Pickled Steel Strip in the company through the application of Failure Mode and Effects Analysis (FMEA).The various possible causes of failure and their effects along with the prevention are discussed in this work. Severity values, Occurrence number, Detection and Risk Priority Number (RPN) are some parameters, which need to be determined. Furthermore, some actions are proposed which require to be taken as quickly as possible to avoid potential risks which aid to improve efficiency and effectiveness of Hot Rolled Pickled Steel Strip processes and increase the customer satisfaction. The prevention suggested can considerably decrease the loss to the industry in term of both money, time and quality.

**Keywords:** Ishikawa diagram, Process FMEA (PFMEA), Pickling Process, Risk Priority Number (RPN)

---

## 1. INTRODUCTION

Failure Mode and Effect Analysis (FMEA) is a process improvement tool to analyze and control the potential impacts from failures. from the FMEA practice it is expected to prevent the possible failures from a product or system after it is implemented. In such a way engineer can improve process by controlling the causes of failures or limiting their negative effects.

Failure mode and effects analysis (FMEA) is commonly defined as “a systematic process for identifying potential design and process failures before they occur, with the intent to eliminate them or minimize the risk associated with them”. The FMEA technique was first reported in the 1920s but its use has only been significantly documented since the early 1960s. It was developed in the USA in the 1960s by national aeronautics space agency (NASA) as a means of addressing a way to improve the reliability of military equipment.

Failure Mode and Effect Analysis is used to identify and analyzed: (a) all possible failure modes in the system/process (b) Effects of these failure modes on the system and (c) how to avoid these failure and/or moderate the effect of the failure system. FMEA is step by step methodology to identifying all potential failure in the process. Effect Analysis refers to studying the consequences or impact of those failures. The advantages of undertaking a process FMEA is to continuously develop product and process consistency thereby increasing customer satisfaction.

Demand on high surface quality cold sheet has been increased sharply in recent ten years because of rapid increase in auto industry. With the progress of hot rolling and cold rolling technologies. The scale must be removed previous to the cold rolling process, since it may produce operative problems and qualitative defects in the material. Effective scale removal is essential for the success, not only of cold rolling, but also of the subsequent annealing and coating operations (Lecourt, 1996). In order to get rid of these oxides, the steel strip is submitted to a critical process called pickling.

During the hot rolling or heat treatment of steel, oxygen from the atmosphere reacts with the surface iron to form a crust that is made up of oxides of iron. This crust is known as scale and need to be removed before steel is further processed in cold rolling mill. Non removal of scale will have the following detrimental effects.

- Scale not only give bad appearance to the product but also accelerate corrosion
- During cold rolling of the strip scale patches affects the reduction with the possibility of the skidding of rolls. Effective scale removal is essential for the success of not only for cold rolling but also of subsequent annealing and coating operations.
- During cold rolling and annealing the scale will produce a dirty surface and cause the rusting of the strip
- During coating of the strip, presence of scale causes poor to total adhesion failure.

## 2. BRIEF ABOUT CASE INDUSTRY

Keshav Metal Pvt. Ltd.-A leading Manufacturer of Hot Rolled Pickled and Cold Rolled Closed Annealed (CRCA) steel strip coils. The motto of the company is to enhance the customer satisfaction by processing and providing Cold Rolled Steel Strip and HR coils of agreed quality on committed Time.

Keshav Metal Pvt. Ltd company came in to existence in 1999 to cater the demand of CRCA strip flat products of mild steel for quality conscious customer. Coils/strip produced by Keshav Metal Pvt. Ltd are used in

Automobiles, pipes & tubes industries, furniture, Rolling shutters, Architectural utilities, and for specialized applications. Keshav Metal Pvt. Ltd. is situated at MIDC area Waluj, Aurangabad, Maharashtra, India

### 2.1 Formation of Improvement Group

To be able to measure, measure, analyze and improve the current situation there is a need of process knowledge. Thus it is decided to form an improvement group containing a variety of competences (sanders D. 2000). The group consists of production engineer, Quality Manager and operators.

## 3. PROCESS FLOW DIAGRAM

Fig. 1. Flow chart for HR Pickled Steel Strip Process

## 4. PROCESS FMEA

The process FMEA was carried out to detect the possible failure mode related to the manufacturing of HR Pickled and Cold Rolled Closed Annealed (CRCA) steel strip operation and prioritizes among them. When working with FMEA the starting point was the process map.

The improvement and quality group carried out the tool by looking the process flow diagram and discussed on the each process. And find out the possible failure modes in each process and gives them the Risk Priority Number (RPN).

The potential failure mode, cause and their effects shown in the FMEA sheet and various types defect and the origin of these defects are explained here in brief.

TABLE 1: Process function and potential failure mode

Process function	Potential failure mode
Pickling	Black scale on surface
	Rust on surface
	Scratch mark
	Under pickling
HR Slitting	Width Undersize
	Width Oversize
	Burr
	Cutter Mark
Rolling	Thickness Undersize
	Thickness oversize
	Skidding mark

### 1) Rusty patches

**Definition:** Corrosion products of iron appears in the form of reddish yellow to black patch on the strip

**Cause of formation:** presence of oil or emulsion carry over on the strip surface promoted by temperature fluctuations, high air humidity and long storage time or delay in next process.

### 2) Black Scale

**Definition:** These are permanent marks that appear on the strip after Pickling.

**Cause of formation:** low acid concentration or weak acid strength during the pickling process. The black Scale on the coil surface are also due to the impurities in the Acid

### 3) Roll mark

**Definition:** They are indentation or depression on the strip of regular form which occur periodically.

**Cause of formation:** foreign particles present between rolls. Improper cleaning of roll and roll grinding.

### 4) Coolant patch

**Definition:** These are Permanent mark that appear on the strip after cold rolling.

**Cause of formation:** Coolant used during rolling are not removed completely.

### 5) Rolled in scale

**Definition:** Scales which are not removed during pickling and is rolled into the surface during cold rolling operation.

**Cause of formation:** Inadequate preliminary de-scaling or pickling of hot strip

**6) Pickling defect:** During the pickling process, the under pickling and over pickling defects are usually the direct results of lack of control over process variables including acid concentrations, Solution temperature and contact time deriving from pickling line speed.

**7) Over pickling:** Pickling line must be maintained as per SOP Pickling tank acid concentration, Hydrogen absorption in sheet and temperature of the pickling bath. Line should not be stopped longer during the pickling process.

## 5. SELECTION OF RANKING

**TABLE 2: Severity and Detection PFMEA Custom Ranking, Customer Satisfaction Examples**

Severity rating		Detection evaluation criteria	Ranking
Effect	Severity Effect on Process	Example	
Hazardous without warning	may endanger operator (machine or assembly) without warning	No monitoring, measurement or sampling.	10
Hazardous with warning	may endanger operator (machine or assembly) with warning	Acceptable Quality Level (AQL) Sampling plan used for sampling Inspection.	9
Very High	100% of material may have to be scrapped, or rework time greater than two hours	100% visual Inspection.	8
High	Material may have to be sorted and a portion (less than 100%) scrapped,	100% visual Inspection with visual Standards.	7
Moderate	Material may have to be sorted and a portion (less than 100%) scrapped, and the rework time less than two hours	100% Manually Inspected using gauges.	6
low	Material may have to be reworked 100% on Process but does not go to customer end	Statistical Process control (SPC) Used in Process With Cpk 1.33 or higher	5
Very Low	Material may have to be reworked 100% with no scrap	SPC used in-Process with Cpk 1.67 or higher	4
minor	A portion of the production run may have to be reworked in process before it is processed	Does not apply.	3
Very minor	Slight inconvenience to process, operation or operator	Does not apply	2
None	No effect	Does not apply	1

**TABLE 3: Occurrence PFMEA custom Ranking**

Probability of Failure	Likely Failure Rates or Rework (Tons)	Rank
Very high: Persistent failures	$\geq 15$ Ton per month	10
	9 -10 Ton per month	9
High: Frequent failures	8-9Ton per month	8
	7-8 Ton per month	7
Moderate: Occasional failures	6-7 Ton per month	6
	5-6Ton per month	5
	4-5 Ton per month	4
Low: Relatively few failures	1.5-2 Ton per month	3
	1-1.5 Ton per month	2
	$\leq 1$ Ton per month	1

Failure Mode Identified and FMEA conducted for each failure mode to calculate the Risk Priority Number of respective Failure Mode. FMEA Identified the potential failure Modes, their causes and the Effects on the system for given Process. Based on the RPN calculation Rust on surface, Black Scale and Under pickling has maximum Risk when Compared to other failure.

**Fig. 2. Pareto Analysis of Failure Modes**

## 6. ROOT CAUSE IDENTIFICATION

Brain storming was conducted and the points were identified and added to the fish bone diagram.

Fig. 3. Ishikawa Diagram for Rusty Patches on the coil after pickling process

## 7. RESULT AND DISCUSSION

Percentage Reduction in RPN

$$= \frac{\sum \text{Initial RPN} - \sum \text{Final RPN}}{\sum \text{RPN initial}} \times 100$$

$$= \frac{1657 - 930}{1657} \times 100$$

$$= 43.87\%$$

Fig. 4. Comparison Between Initial Vs Final RPN

**TABLE 4: FMEA Sheet**

Process Function	Potential Failure Mode	Potential Effects of Failure	S e v	Potential Cause / Mechanism of Failure	O c c u	Current Process Controls Prevention	Current Process Controls Detection	D e t e	R P N	Recommended Actions	Action Results				
											Action Taken	S e v	O c c	D e t	R P N
Pickling	Black scale on surface	Roll skidding during rolling process- Internal ppm	8	Low acid temp.	4	No specific control for low acid temperature	Visual check	7	224	maintain acid temperature within 42-48 deg.	temperature controller Installed	8	3	7	168
	Rust on surface	Customer Rejection	8	Acid and water not removed properly on strip	8	Wiper provided at acid tank exit	visual	7	448	Change Wiper	Replace wooden wiper with Rubber wiper	8	2	7	112
	Scratch Mark	Internal PPM	5	Foreign particle trapped in wiper	4	wiper change periodically	visual and inprocess inspection	8	160	wiper change daily	wiper changed	5	2	8	80
	Under Pickling	Customer Rejection	7	weak acid strength	4	No specific control for weak acid strength	check once per day with hydrometer	9	252	Temp & strength matrix to be developed and Implemented	Maintain acid strength range 10%-18%	5	3	8	120

## 8. CONCLUSIONS

Cause and Effect Diagram helped to think through causes of a problem thoroughly by pushing us to consider all possible causes of the problem, rather than just the ones that are most obvious.

FMEA analysis easily help in improving the efficiency of the manufacturing process and quality of the coil thus decreasing the number of defective and saving of rework cost and time. For each specific process the preventions suggested in the FMEA table can considerably decrease the loss to the manufacturing industry in terms of both money and time.

FMEA identified the potential failure modes, their causes, and the effects on the system for given process. Based on RPN calculation Rust on surface, Black scale, and under pickling had maximum risk when compared to other failure.

After performing process FMEA and action taken, the Risk Priority Number (RPN) reduce up to 43.87% and save process failure expected cost up to maximum 22, 200 Rs/ month or 2, 66, 400 Rs/ Year. That means 66.46% material Rejection/ Rework cost save after process FMEA.

**Abstract:** The success of any industry relies upon products that are as failure free as possible. The cost associated with defective products from liability or lost customer stand point can have unexpected impact on industry. In this paper, the quality problems raised in producing cold rolled annealed coils due to deficiencies in manufacturing process at an industry are addressed using Process FMEA technique. The processes considered for this analysis are annealing and finishing processes such as skin pass/temper rolling and slitting. The potential failure modes for each process are listed by brainstorming among team members and observing past rejection data. Then the Cause and effect of each failure are evaluated and noted in the FMEA sheet. The quantification of each failure is carried out by assigning rankings for the Severity (S), Occurrence (O) and Detection (D) of each the failure mode or its cause. The calculated Risk Priority Number (RPN) determines risk associated with these failure modes and corrective actions are determined for the failure modes having high RPN value in descending order up to the acceptable range of RPN. The fishbone diagram and Why-why analysis for prioritized failure modes determines corrective actions. After implementing these actions it is found that the quality is considerably improved and the loss to the industry in terms of both money and time is decreased.

**Keywords:** Cold Rolled Annealed, Process FMEA, Risk Priority Number, Slitting, skin pass rolling

---

## 1. INTRODUCTION

Process FMEA is used to analyze the existing or new process and is driven by function of a process. It focuses on the risk of potential failure modes associated with the process safety, effectiveness, efficiency and problems with the functions of a product caused by the problems in the process.

Each manufacturing defect is a failure mode of a process, since the process should not produce it. Using Process FMEA an engineer can solve these failures occurred due to manufacturing process by deliberately controlling the cause of failure or limiting their bad effects

This paper includes application of process FMEA to a manufacturing industry producing Cold Rolled and Annealed coils to reduce rejection and reworks due to its quality problems. The processes considered for study is annealing and finishing processes such as skin pass/temper rolling and slitting. Process FMEA is applied systematically in step-by-step manner to minimize operational defects occurring during these processes. The potential failure modes for each process are listed by brainstorming among team members and observing past rejection data. Then the Cause and effect of each of failure are evaluated and noted in the FMEA sheet. The quantification of each failure is done by assigning rankings for the Severity (S) of the failure, the Occurrence (O) or frequency of the failure and

the Detection (D) i.e. probability of detecting the failure mode or its cause. The Risk Priority Number (RPN) is calculated by multiplying the assigned Severity, Occurrence and Detection ranking for each failure modes which determines risk associated with these failure modes. Once all Risk Priority Numbers are calculated for the considered failure modes, corrective actions are determined for the failure modes having high RPN value in descending order up to the acceptable range of RPN. The goal of a corrective action is to achieve suitable reduction in risk of the failure mode.

### 1.1 Objectives of Project Work

The main objective of our project work is make improvements in process to reduce rejection/reworks in the annealing, skin pass rolling and slitting operations using FMEA. To achieve this following sub-objectives are formulated.

- Address all potential failure modes in the processes
- Evaluate the effect of each failure mode
- Prioritize failure modes based on its RPN
- Suggest and implement necessary actions
- Verify the effectiveness of implemented actions.

## 2. LITERATUREREVIEW

The Failure mode and Effect Analysis was developed and implemented for the first time in 1949 by U.S. Army and later executed in Apollo space mission to moderate the risk. In 1950s the increasing attention given to safety and need to prevent predictable accidents in aerospace industry led to the development of FMEA methodology. Later it was introduced as key tool for increasing product quality and efficiency in manufacturing processes.

Arunachalam and Jegadheesan, 2006 presented a case study with reliability and cost based approach for the cooling system of passenger transport vehicles using data collected from state transport corporation depot. Teng et al., 2006 propose that the issues regarding reliability of a product must be included before the completion of design stage and one has to confirm that design requirements are met. Anette von Ahsen, 2008 implemented the cost-oriented FMEA to improve quality management. In order to suggest an improvement actions they included costs arising from faults detected by the customer, costs of faults detected within the boundaries of the company and costs associated with false positive inspection results in the evaluation of potential failures. Piyush et al., 2012 used FMEA methodology and implemented in a foundry for reducing rejections of bushes and to improve operational performance of the process. The problems identified in the various steps of core making process contributing for high rejection are studied and analyzed in terms of RPN to prioritize the attention for each of the problem. The criteria used to evaluate these problems or causes are the amount of damage caused to the production in terms of core rejection or lost production volume and subsequent monetary loss. Tejaskumar S. Parsana, et.al., 2014 has identified and eliminated current and potential problems from a manufacturing process of cylinder head in the company through the application of Failure Mode and Effects Analysis (FMEA) for improving the reliability of sub systems in order to ensure the quality which in turn enhances the bottom line of a manufacturing industry..

Puvanasvaran et.al., 2014 integrated the Poka Yoke concept to guide the action of engineers in the case of every potential failure that might be generated from the process input. S. B. Chikalthankar and G. S. Sawadadkar, 2015 used FMEA for process development and implement this tool in precision bearing manufacturing company. They integrated Statistical Process Control (SPC) for evaluating occurrences of failure in the needle cutting operation. Govind S. Dhage and S. B. Chikalthankar, 2016 addressed the limitations with the conventional FMEA approach. They tried to improve the representation of failures, and to evaluate these failures with consistent and meaning full risk evaluation criteria to facilitate cost based decisions. Banduka, N., et.al., 2016 proposed an integrated lean approach to Process Failure Mode and Effect Analysis

(PFMEA) for automotive industry for solving specific shortcomings. Some of those lean tools and principles integrated in PFMEA are: GenchiGenbutsu, Kaizen, standardized work, Jidoka and 5 why. This new PFMEA approach has proven to be very good and practical combination for identifying and fixing problems and failures.

## 3. BRIEF ABOUT THE INDUSTRY

Keshav Metals Pvt. Ltd. is a leading manufacturer of Cold Rolled Closed Annealed (CRCA) steel coils. The industry is situated at MIDC area, Waluj, Aurangabad, Maharashtra, India. Coils produced by Keshav Metals Pvt. Ltd are used in pipes & tubes industries, automobiles, rolling shutters, furniture, architectural utilities, and for specialized applications. The figure 1 shows the flowchart of the process at the industry. The input is pickled cold rolled coils which are annealed, skin passed and slit to required width and dispatched.

Fig. 1. Process flowchart at industry

## 4. METHODOLOGY

### 4.1 Brainstorming Potential Failure Modes

A potential failure mode represents the way in which the process could fail to perform its intended function leading to defective material. The failure modes of the product which could originate during processing are identified and listed as given in table 1 for each process by brainstorming and observing customer complaints and line rejection/rework records.

**TABLE 1: Brainstorming to find potential failure mode**

S N	Process	Potential Failure Modes
1	Annealing	High/low Hardness
		Black patches of coolant on surface
		Sticking of overlapping layers of coil
		Coil Buckling
2	Skin Pass / Temper Rolling	Thickness undersize/ oversize
		Thickness variation along rolling direction
		Thickness variation across width
		Roll marks, dents on strip Scratch marks
3	Slitting	Oversize/ undersize width
		Width variation throughout coil
		Burr on the edge
		Cutter Mark on surface
		Interrupted trimming
		Camber

#### 4.2 Ranking Criteria

The criteria used for ranking the severity, probability of occurrences and detection of failure modes are given in table 2 to 4.

**TABLE 2: Process FMEA severity evaluation criteria**

Rank	Effect	Criteria
10	Hazardous to operator	May endanger operator without warning
9		May endanger operator with warning
8	Major disruption	100% of product may have to be scrapped.
7	Significant disruption	100% of production run may have to be rework. (Major rework)
6	Moderate disruption	100% of production run may have to be rework. (Minor rework)
5		A portion of the production run may have to be scrapped
4		A portion of the production run may have to be reworked (Major rework)
3		A portion of the production run may have to be reworked.( Minor rework)
2	Minor disruption	Slight inconvenience to process, operation or operator
1	No effect	No effect on product

**TABLE 3: Process FMEA occurrence evaluation criteria**

Rank	Likelihood of Occurrences	Likely Failure Rates (Rework/months)
10	Very high (failure is almost inevitable)	$\geq 10$ Ton
9		8.1-10 Ton
8	High (repeated failures)	7.1-8 Ton
7		5.1-7 Ton
6	Moderate (occasional failures)	4.1-5 Ton
5		3.1-4 Ton
4		2.1-3 Ton
3	Low (relatively few failures)	1.5-2 Ton
2		1-1.5 Ton
1	No known occurrences on similar products or processes	$\leq 1$ Ton

## 5. PERFORMANCE ANALYSIS

Using these criteria, Risk Priority Number is calculated and value entered in FMEA sheet.

### 5.1 Prioritize the failure mode

The calculated RPN is be used to identify where the team should focus first for improvement. The higher the RPN, higher the relative risks. The table 5 below shows failure modes taken on priority for improvement.

**TABLE 4: Process FMEA detection evaluation criteria**

Rank	Likelihood of Detection	Criteria for evaluation
10	Almost Impossible	No current process control/ detect failure mode
9	Very Remote	Failure mode/cause is not likely to detect at any stage.
8	Remote	Failure mode detection in post-processing by operator-visual/audible/tactile means
7	Very Low	Failure mode detection post-processing by operator-using visual and variable gauging
6	Low	Failure mode detection post-processing by automated controls; stop process to prevent further defectives
5	Moderate	Failure mode/cause detection in-process by operator-visual/audible/tactile means only
4	Moderately High	Failure mode/cause detection in-process by operator-using variable gauging or automated controls
3	High	Failure mode/cause detection in-process by automated controls & automatically stop line
2	Very High	Failure mode/cause detection in-process by automated controls; prevent discrepant material from being made
1	Almost certain	Discrepant materials cannot be made because process has been error proofed

**TABLE 5: List of defects taken on priority**

S.N.	Type of defect	RPN
1	Width Variation during slitting	432
2	Black Patches on coil surface after annealing	252

#### 5.1.1 Width variation during slitting

The potential causes of width variation in slitting operation are brainstormed and summarized in fishbone diagram as shown in figure 2. From this the root cause for width variation is found as cutter/arbor deflection during operation and machine vibration. Therefore to eliminate problem of width variation due to arbor deflection during operation, the slitting setup is made more robust by providing horizontal beam as shown in fig 3(b) which acts as support to arbor holders during slitting operation. Figure 4 shows the run chart and figure 5 represents the histogram of width variation analysis before and after performing corrective action for slitting process. The histogram (b) shows that the variation in width during slitting operation is reduced and size is within the specification limits

#### 5.1.2 Black patches on coil surface after annealing

The fishbone diagram shown in figure 6 represents the potential causes that can leads to black colored coolant patches on coil surface after annealing. From this it is found that the residual coolant patches on surface of annealed strip is due to poor volatilization of rolling coolant and its burning on coil surface during annealing of tight coil in bell-type furnaces. This shows up as a carbon deposit on the strip surface in the form of black colored patches on the coil surface.

This problem of black colored patches on annealed coil surface is depends on how well the emulsions and other residues are removed during heating and purging stage of annealing and is therefore referred to the rolling conditions and the tension during coiling at the cold rolling mill.

Therefore it is advised to control the use of coolant and maintain lower coil tension during winding to get better surface cleanliness after annealing. Further this problem can

be prevented by providing coil winding tension indicator and controller at cold rolling mill stand.

(a)

(b)

Fig. 4. Run chart for slitting (a) before and (b) after PFMEA

Fig. 5. Histogram of width variation analysis (a) before and (b) after corrective action

Fig. 6. Cause and effect diagram for black patches on coil after annealing

## 6. RESULTS

After implementing corrective actions, risk priority numbers are recalculated to see the impact of the improvement on process. The RPN after improvement are calculated and mention in the final FMEA sheet (table 6). Comparison of RPN's before and after corrective action is shown by line graph in figure 7.

### 6.1 Percentage Reduction in RPN

The reduction in RPN after performing recommended

action represents the effectiveness of FMEA technique. It is calculated as Eq. 1

Percentage Reduction in

$$\text{RPN} = \frac{\sum \text{Initial RPN} - \sum \text{Final RPN}}{(\sum \text{RPN initial})} \times 100$$

$$= \frac{1527 - 933}{1527} \times 100 = 38.89\%$$

Therefore after performing FMEA about 38.9% risk of failure mode is reduced.

**Fig. 7. Comparison of RPN's before and after PFMEA**

**TABLE 6: Final Process FMEA Sheet**

Process & its Function	Potential Failure Mode	Potential Effects of Failure	Severity	Potential Cause	Occurrence	Current Process Controls Prevention	Current Process Controls Detection	Detectability	RPN	Recommended Actions	Action Results				
											Action Taken	Severity	Occurrence	Detectability	RPN
Annealing : Anneal cold rolled coils to remove residual stresses	a. Hardness high/low	Customer Rejection	7	Annealing cycle not as per material properties	2	Annealing cycle defined according to material hardness and chemical properties	Hardness checking after annealing	4	56			7	2	4	56
	b. Black Patches on surface	Problem during coating at customer end	7	Contamination of surface by oil,dust, coolant/ Tight winding of coil	6	Black patches cleaned during temper rolling/skin pass rolling	Visual detection at temper mill stand	6	252	Lower the tension in coil during winding at cold rolling mill to allow to remove and vaporize coolant	Coil is loosely wound at last pass at cold rolling mill.	7	1	6	42
	c. Sticking	Sticky marks on surface	2	wrong selection of temp. cycle for annealing / Tight winding of coil	3	Annealing cycle defined according to material hardness and chemical properties & No specific value defined for tightness of coil	During skin pass	6	36			2	1	6	12
	d. Coil buckling	Coil shape change	4	Coils are not supported. Convector plates are not properly positioned	2	Defect removed in skin pass rolling due to tension	Visual	6	48			4	2	6	48
Skin Pass: Roll to finish thickness size and provide desired surface finish to surface	a. Thickness Over/under size	Customer rejection	7	Wrong roll gap setting	2	Scale provided for adjusting gap between rollers	Thickness measurement 3 times during rolling	4	56			7	2	4	56
	b. Thickness variation along rolling direction	Customer Rejection	7	Roller deflection, rolling speed variation, Deformed rollers	2	Roller inspection Included in Preventive maintenance	Thickness measurement 3 times during rolling (No continuous monitoring)	9	126	provide sensor for continuous monitoring of output thickness	X-bar R-charts drawn and Process capability found to check current machine condition	7	2	9	126
	c. Thickness variation across width	Customer Rejection	7	Roller axis not parallel	2	Two different scales for roll gap setting	Measure thickness at both edges and at center of strip	5	70			7	2	5	70
	d. Roll mark	Roller impression on coils.	5	Chatter/dresser marks on roll when grinding	2	Vial inspection	Trial pass after redressing of rollers	5	50			5	2	5	50
	e. Scratch Mark	Scratches on throughout the coil	7	Foreign particles entrapped in wiper	2	Clean wiper before stating skin pass rolling	Visual detection during process	5	70			7	2	5	70
CR Slitting: slit coil to required width	a. burr	Line Rejection	5	Horizontal and vertical clearance setting not proper	3	Standard clearance value provided to operator as per material thickness.	Visual detection at slitting output	5	75			5	3	5	75
	b Interrupted trimming	Line Rejection	6		2			4	48			6	2	4	48
	c. Width over/under size	Line Rejection/scrap generation	5	Cutter setting not correct	3	Paper shims are used to size adjustment	Measure width by digital vernier caliper	4	60			5	3	4	60
	d. Width Variation	Customer Rejection	8	cutter deflection/ arbor deflection/ machine condition	6	Three times inprocess width measurement	Visual	9	432	Minimize cutter deflection/machine vibration	Process capability index measured. Setup is made robust by reducing vibrations	8	1	9	72
	e. Camber	Strip not guided in die at customer end. Customer Rejection	7	Cutter clearance not uniform/ Defect in master coil	2	No any preventive measures. Camber if occurred then removed after slitting process	Camber measured after slitting	7	98			7	2	7	98
	f. Cutter Mark	Customer/line Rejection	5	Improper stripper ring selection/ Incorrect vertical clearance	2	stripper rings are selected based on size of cutter & Visual inspection and adjusting vertical clearance	Vertical Clearance setting by judgment and trial-error	5	50			5	2	5	50
Total									1527						933

## 7. CONCLUSIONS

This paper provides systematic approach for the estimation, analysis, and evaluation of risks. This process FMEA document can be helpful for future use and continuous process improvement in the industry.

The implementation of process Failure mode and Effect Analysis in CRCA strip manufacturing industry gives following outcomes

- Based on RPN calculation width variation in slitting operation and black colored coolant patches had maximum risk when compared to other failure.
- Implemented action decreases occurrence of defective material production in the slitting operation by providing horizontal support to the vertical arbor holders which acts as a beam restricting cutter and arbor deflection during slitting and make the process more robust.
- Statistical Process control (SPC) gives the estimation of variation in the output width of coil during slitting operation.
- The residual coolant which remains on strip surface gets evaporated during heating, on keeping low tension during winding at cold rolling mill. Therefore quality and cleanliness of coils after annealing process is improved.
- After implementing recommended action in Process FMEA about 38.9% reduction in Risk Priority Number (RPN) is observed.

# Study of Influence of Deep Cryogenic Treatment on Hardness and Microstructure of Various Carbon Contain Materials: A Review

Sameer M. Sayyad, Vivek V. Ahire, S. A. Patil.

Department of Mechanical Engineering  
Government college of Engineering, Aurangabad, Maharashtra, India

**Abstract:** The objective of this paper is to understand the effects of cryogenic treatment particularly on hardness and microstructure of various carbon contain different materials like ferrous alloys, different steels etc. This article provides a review on the research work of cryogenic treatment process. Study shows that different results in terms of improvement in hardness and microstructure which are mainly depends on carbon percentage, austenizing temperature, soaking time and tempering temperature.

**Keywords:** Cryogenic treatment, Austenizing temperature, Microstructure, Phase Transformation, Hardness, soaking time.

## 1. INTRODUCTION

The importance of deep cryogenic treatment process is increases from last few decades in the application of carbon contain alloys, Cryo process is considered as add-on process over the conventional heat treatment process. Cryogenic processing is a sub-zero heat treatment that affects the entire cross-section of materials and components, with the objective of improving mechanical properties such as hardness, wear resistance, by causing micro structural changes into different stable or meta- stable states.[R. Thornton et al., 2013] In cryogenic treatment process liquid nitrogen (LN₂) is generally used as cryo-fluid for treatment of material.

Three sub-zero treatments can be categories according to temperature as:

1. Cold treatment (273–193K),
2. Shallow cryogenic treatment (193–113K)
3. Deep cryogenic treatment (113–77K) which is invariably referred to as DCT [R. Thornton et al., 2013].

In this process transforms the retained austenite into martensite and causes the precipitation of finely dispersed carbides [1]. In first stage substance is cooled down up to -130 °C, retained austenite is transformed into martensite as that occur in conventional sub-zero heat treatment process. In second stage of substance is cooled up to -196°C, in this process primary martensite decomposed through a time-dependent transformation.[ R. Thornton et al., 2013], Deep cryogenic treatment makes the retained austenite vanish.[ A Akhbarizadeh et al., 2009]

## 2. LITERATURE REVIEW

B. Podgornik et al., 2016 studied the effect of DTC on different tool steel material and it is found that material having low carbon contain and higher W and Co contain cold-work tool steel (A1) shows great improvement in fracture toughness and and at the same time maintains the high hardness. From another sample (A2) with higher C contain DCT shows the negative effects in hardness, and high speed steel (B1) shows almost no effects on its property.

**TABLE 1: Nominal chemical composition of tool steels used in the investigation (in wt %) [3]**

Material	C	Si	Mn	Cr	Mo	V	W	Co
A1	0.85%	0.55%	0.40%	4.35%	2.80%	2.10%	2.55%	4.50%
A2	2.45%	0.55%	0.40%	420%	3.80%	9.00%	1.00%	2.00%
A3	1.65%	0.60%	0.30%	4.80%	2.00%	4.80%	10.40%	8.00%

**Fig. 1. Microstructure of low carbon contain cold work tool steel (A1) after (a) quenching, (b) conventional triple tempering and (c) DCT and single tempering [3]**

Talking about microstructural change it is found that low carbon contain tool steel can be related to formation of finer needles like martensite and martensitic transformation accompanied by plastic deformation of primary martensite. While for high carbon contain cold work steel high volume fraction of more stable MC carbides which may change precipitation kinetics lead to properties impairment after DCT.

Seyed Ebrahim et al., 2013 Studied the effect of DCT on 45WCrV7 material. 45WCrV7 is mostly used for cutting

blades and punching tools manufacturing. In this research they have taken different soaking and tempering times for analysis purpose to improve mechanical property and microstructure of material. From study it was observe that maximum toughness could be obtained by increasing soaking and tempering times. Toughness is improved due to pullout of high population density of SCs occurs. Hardness can be effectively increased by increasing soaking or tempering times, but leads to increase in production time results in high cost. So to reduce production time and cost increase in tempering time is fesibke alternative.

**(a)**

**(b)**

**Fig. 2. DCT and double DCT (a) cycles and (b) flow chart for experimental procedure [4]**

Precipitation of the SC was primarily due to the expansion resulting from transformation of the retained austenite into martensite. It is also observed that for the tool steel, double DCT had almost no effect on significance effect on microstructure of 45WCrV7.

Chen-hui et al., 2015, studied the Effects of deep cryogenic treatment on microstructure and properties of WC-11Co cemented carbides with various carbon contents

**TABLE 2: Properties of WC–11Co with various carbon contents before and after deep cryogenic treatment [5]**

Sample	Mass fraction of Carbon %	Composition	Hardness
UT1	4.45	WC+Co+Co ₃ W ₃ C	87.9
UT 2	4.92	WC+Co	87.15
UT3	5.25	WC+Co+Graphite	87.01
DCT 1	4.45	WC+Co+Co ₃ W ₃ C	88.25
DCT 2	4.92	WC+Co	87.20
DTC 3	5.25	WC+Co+Graphite	87.25

In this study they have taken three different samples with various carbon percentage and composition. In table 2 UT stands for untreated sample and DCT stands for deep cryogenically treated sample. From study it was found that the hardness values in the deep cryogenically-treated sample were increased by 0.39%, 0.06% and 0.28%, respectively.

According to researcher it depends on two factors one is attributed to the compressive residual stress, which is induced by the large difference of thermal expansion coefficient between WC and Co phases during the DCT progress, second is densification of Co phase has an

important effect on the hardness of samples. Deep cryogenic treatment enhances the hardness and bending strength of the alloys.

Talking about microstructure it was observed in Figure 2 that microstructures of the sample with various carbon contents before and after deep cryogenic treatment. In the low carbon alloys, it can be observed that from Figures. 2(a1) and 2(b1) that  $\eta$ -phase is more in cryo treated sample, which are induced by martensite phase transformation in the DCT. In the carbon-rich alloys, as shown in Figures. 2(a3) and (b3), free carbon is formed while the  $\eta$ -phase disappears in the sample.

**Fig. 2. SEM images of WC–11Co cemented carbides with low and high carbon contents before and after deep cryogenic treatment: (a1) low carbon alloy UT-1; (b1) low carbon alloy DCT-1; (a3) rich carbon alloy UT-3; (b3) rich carbon alloy DCT-3[5]**

After studying microstructure it was found that WC grains are refined into triangular prism with sound edges via the process of spheroidization, but WC grain size has no evident change compared with that of untreated alloys.

M. El Mehtedi et al., 2012 done the Analysis of the effect of Deep Cryogenic Treatment on the hardness and microstructure of bX30 CrMoN 15 1 steel, in this research they found that the microstructure of the WQ material austenized at 1200 °C; the structure is partly martensitic, with a substantial fraction of retained austenite. The microstructure of the steel austenized at 1200 °C, after cooling in air (AC condition) did not show any significant difference. Deep Cryogenic treatment results in the almost complete transformation of the retained austenite, and also appears to affect the precipitation sequence. The maximum peak hardness is obtained after tempering the DCT samples at 450–500 °C. A simple model, which takes into account the single contributions of martensite, retained austenite and carbides carbonitrides, was able to describe the variation in hardness as a function of austenizing temperature.

Yang Gao et al., 2016 studied the effects of deep cryogenic treatment on the microstructure and properties of WC-Fe-Ni cemented carbides, Sample is deep cryogenically treated for around -196°C for three different cryogenic treatment time 2 hrs, 12 hrs, 24 hrs. from study it is found that as deep cryogenic time increases the martensitic phase transform from  $\alpha$ -(Fe, Ni) has taken place. The  $\gamma \rightarrow \alpha$ -(Fe, Ni) phase content in the binder phase gradually increases from 12.7% to 86.8% (wt.%) and W particles precipitate from the binder phase and hardness improved around 20%. The change of the properties can be primarily attributed to the fact that the martensite phase transformation from  $\gamma$ -(Fe, Ni) to  $\alpha$ -(Fe, Ni) and precipitation of W particles in the binder phase improve the hardness and strengthen the binder phase during the deep cryogenic treatment.

### 3. CONCLUSION

Cryogenic treatment process is considered as add-on process over the conventional heat treatment process. The results of this broad review on the effects of cryogenic treatment on hardness and microstructure indicates that

1. Deep cryogenic treatment enhances the hardness considerably than the other conventional heat treatment process,

2. Increased in hardness is significantly high in case of low carbon contain material compare to higher carbon contain.
3. Improvement in hardness is observed due to transformation of retained austenite into martensite at microstructural level.
4. Amount of hardness improvement is also depends on various parameters like soaking time, rate of heat, austenizing temperature, soaking temperature, grain size, tempering time, tempering temperatures etc.

# Modeling, Analysis & Simulation of Micro Resistance Butt Welding Setup

Rahul Prasad, Rajat, Rajeev Agrawal

Department of Production Engineering  
Birla Institute of Technology, Mesra, Maharashtra, India

**Abstract:** This paper aims to provide a robust and flexible design of micro resistance butt welding setup. Resistance butt welding has been extensively used for joining two metal pieces. This paper gives an insight about the analysis and simulation of resistance butt welding process including their implications and limitations. A detailed simulation of the entire resistance welding process which includes analysis of thermo physical properties, thermal conductivity, coefficient of thermal expansion, electrical resistance, specific heat, tensile strength, etc. have been done. For numerical simulation & analysis of welding process parameters, two low-carbon steel work pieces have been taken in a symmetric butt welding model and an electro-thermal finite element method has been developed. The simulation results reveal that the maximum weld zone diameter occurs at the end of the heating stage which is an irreversible phenomenon. Resistance butt welding confers permanently leak proof surface. Besides proposing a versatile setup, this paper fulfills an identified need to do an overall modeling and analysis of resistance butt welding setup.

**Keywords:** Resistance butt welding, resistance welding, modeling, analysis, micro setup.

## 1. INTRODUCTION

In today's era, welding has found its boundless use. General day to day use items, e.g., automobile cars, aircrafts, ships, electronic equipment, machinery, household appliances, etc., depend upon welding. Welding is applied in vast areas due to its advantages like, easy to be done, can be made as strong as parent metal, economical, fast in nature, etc. Today, welding had taken over riveting and other fastening processes. Earlier bridges, ships and boilers were riveted, are now welded. Welding can produce a 100% efficient joint which is difficult to make by riveting [Khanna, 2009]. There are 35 different welding processes. This paper focus on Resistant butt welding analysis only. Compared to typical fusion welding processes, the RBW process has advantages such as speed, ease of control, fewer defects, enhanced weld properties, simplicity of equipment and the ability to join difficult-to-weld materials. These qualities make RBW an appropriate welding process to be utilized in various industrial settings; such as assembling automotive bodies, sealing of containers of high-level nuclear waste, joining steel materials, super alloy materials, aluminum alloys and parts made of dissimilar materials [8]. Kanne expressed that in comparison with fusion welding processes, the chemical composition and metallurgical properties are not significantly changed leading to better mechanical properties. Simplicity, welding speed, capability of remote control and independence of welding quality from the operator skill are the other advantages of this process [Kanne Jr, 1994]. He pointed out that advantages of RBW, compared to fusion welding processes, include fewer defects and stronger welds with a faster and

more reliable process [Kanne Jr, 1994]. Resistance welding didn't require fluxes shielding gasses or filler materials, so metallurgy of the weld depends only upon parent material. At present time, welding practice is divided into about 70% Arc welding with balance between Resistance welding and Oxyacetylene welding [Khanna, 2009].

In this study evaluation of RBW and its different parameters is investigated theoretically. This paper also aims to give a robust and flexible design of micro setup of resistance butt welding, which can also be used for seam welding with some minor changes.

## 2. AFFECTING PARAMETERS

There are four parameters that affect the RBW process:

- **Resistance:** This is responsible for generation of heat in the process. But in the RBW process there are three resistance working simultaneously. First Resistance at the contact of electrode and workpiece ( $R_1$ ), second is the resistance of workpiece to the flow of current ( $R_2$ ) and third one is the resistance at the faying surface ( $R_3$ ). Here,  $R_1, R_2 \ll R_3$ .

So, contact resistance depends upon current and upset pressure. Rudzitis et al. (1998) gives an equation to relate contact resistance and applied pressure  $P$ .

$$R_c = \frac{k_r \rho E^2}{[P 2a_1(1 - \nu^2)]^2} \left( \frac{R_a}{s_{m1}} \right)$$

Where  $a_1$  is the contact radius of the electrodes in spot welding,  $\rho$  is the resistivity of the material,  $k_r$  is the

surface anisotropy coefficient,  $R_a$  is the surface roughness,  $S_{ml}$  is the spacing parameter between surface peaks,  $E$  is the Young's modulus and  $\nu$  is the Poisson's ratio. So, from above equation it is visible that  $R_c$  is inversely proportional to applied pressure.

- **Current:** - As per joule's law, heat energy generated depends upon square of current applied. So, current is another important factor. The step-down transformer is used for current. While other parameters are constant, the temperature is regulated by controlling the magnitude of current.. The current used in the welding process is optimized. Mohsen et al., (2010) showed that with increasing the electrical current in the heating stage, mechanical strength of the joint increases to a specific limit and then decreases with a mild gradient, Fig2. Actually, excessive increase in the current causes melting of the mating surfaces and so the gradual drop in the mechanical strength [Sharifitabar et. al, 2011].

Fig. 2. Effect of variation of electrical current in heating stage on tensile strength.

- **Pressure:** - Pressure permits the weld to be made at lower temperature. It also provides a forging action and thus reduces weld porosity. Little electrode force can lead to surface burning and pitting of the electrodes. On the other hand, too high electrode force decrease the contact resistance thus resulting in decreased total heat generated at faying surfaces. Sharifitabar et al., (2011) shows that with increasing of the upset pressure, strength of the joint increases firstly and then decreases, shown in Fig 3.

Fig.3. Effect of upset pressure on tensile strength of the joint.

- **Time:** - It is also referred to as cycle time. It consists of four stages: -

- Squeeze time:* - It is the time between the initial application of the electrode pressure on the workpiece and the initial application of current to make the weld.
- Weld time:* - During this period welding current flows through circuit.

Mohsen et al., (2010) also shows the variation of tensile strength verses time of heating or welding. It reveals that maximum tensile strength increases with a mild gradient until the time reaches a specific value [Sharifitabar et al., 2011], shown in fig 4.

- Hold time:* - It is the time during which force act at the point of welding after the last impulse of welding current ceases.

The effect of post-weld heating time on the tensile strength is shown in Fig 5 [Sharifitabar et al., 2011].

- Off time:* - It is the interval from the end of the hold time to the beginning of the squeeze time for the next welding cycle.

Fig. 4. Effect of variation of heating Time on tensile strength

Fig. 5. Effect of variation of post weld time on tensile strength

Fig. 6. A simple resistance spot welding cycle

Fig. 7. Micro setup of RBW

### 3. MATERIAL AND WELDING CONDITION

Both the rods used are of low carbon steel so their micro structures comprises of pearlite and ferrite phases. Material properties are employed in their electrical-thermal-mechanical model as presented below. In order to increase the accuracy, thermo physical properties, including thermal conductivity, coefficient of thermal expansion, electrical resistance, specific heat, density, elasticity of yield stress and Poisson's ratio are assumed to be temperature dependent. For the second stage simulation and testing of the tensile strength, the ultimate strength of the low carbon steel was chosen to be 400MPA. From the simulation results drawn, the results inferred has been depicted below in the form of graph.

### 4. NUMERICAL RESULTS AND SIMULATION

In order to exemplify the heat generated in the contact faying surfaces under different phases, the simulation process was carried out. The figure below shows the temperature distribution in the weldment at three different times during the whole welding process. In the beginning it was observed that the temperature at the center of the faying surface increased very fast. As shown in the figure 7, the temperature is maximum after 12th cycles at a position away from the center line along the faying surfaces. Here, the heat generated along the contact line of the of the faying surfaces is due the contact resistance. It is inferred that on reaching then first half of the 14th cycle, the temperature level exceeded 350°C. From figure 8, it is clear that at the end of the heating time, i.e, 24th cycle, the temperature of the faying surfaces reaches to 765°C. This stage shows the joint point of low carbon steel which shows that the weld zone starts at this temperature level. Figure 9 shows the typical temperature distribution in the weldment at the end of the post weld heating time. While examining the work pieces interface, the maximum temperature is found at the central region which further drops to a lower value at the periphery. Figure 10 shows the temperature changing histories at three different locations. The computed results indicate that there was a difference in the temperature scale during welding. The peak temperature is observed at the center typically at the end of the heating time ( 24th cycle). After this there is no significant increase in the heating rate during the post weld heating time and the post weld heating current. Consequently there was no further increase in the weld zone size during the post weld heating time and the post weld heating current. From figure 10, it can be easily inferred that the maximum temperature of point 1 is about 1080°C. The nodes temperature decreases slowly during the post welding heating stage and its maximum temperature reaches to 680°C at the post welding heating stage. From this result, it can be revealed that the size of the simulated weldment at the end of the post heating stage is smaller than be at the heating stage. With the examination of the thermal history, it can also be inferred that the maximum weld zone diameter occurs at the

Fig. 7. Temperature distribution at 12th cycles of welding process.

Fig. 8. Temperature distribution at 24th cycles of welding process.

Fig. 9. Temperature distribution at 12th cycles of post-weld heating process.

Fig. 10. Temperature histories at three location in UW process.

end of the heating stage which is an irreversible phenomenon. These simulation results demonstrate that the magnitude of the post heating current and the post weld heating time should be selected after careful examination of mechanical and metallurgical properties of the weldment.

## 5. RESULT & CONCLUSION

In this paper, modeling and analysis of micro RBW setup was carried out. It is found that RBW has many advantages over other welding processes. It can be used for large varieties of metals and alloys like stainless steels (including A-286), super alloys (including TD nickel), refracting metals (including tungsten) and aluminum alloys (including 2024).

The paper also gives a deep analysis of various affecting parameters of RBW, and how they can be controlled to give a good weld. The design of micro RBW setup was also proposed which is robust and flexible in nature. Besides, the simulation of the entire welding process was also carried out and various graphical proven results were found out. This design could also be used for seam welding process with some minor attachments and changes.

# Lean Six Sigma Implementation Barriers: An Integrated Approach of ISM and Fuzzy MICMAC

S.J. Raval, Ravi Kant

Department of Mechanical Engineering  
Sardar Vallabhbhai National Institute of Technology, Surat, Gujarat, India

---

**Abstract:** The aim of this paper is to identify Lean Six Sigma barriers (LSSBs) to inspect interrelationships among these barriers and classify these barriers into driving power and dependence power using an integrated interpretive structural modeling (ISM) and fuzzy Matriced Impacts Croisés Multiplication Appliquée à un Classement (MICMAC) methodology. While the ISM methodology analyses the interactions among the LSSBs, fuzzy MICMAC analysis is employed to obtain insights into the dependencies among the LSSBs. A total of ten LSSBs were identified through the literature review. The research shows LSSBs having high driving power and low dependence have strategic importance because of their driving nature, while the LSSBs having high dependence and low driving power are more performance orientated. Therefore, it is the responsibility of LSS executives to address the high driving power LSSBs for the enhancement of LSS performance. This categorization provides a useful tool to top management to differentiate between independent and dependent LSSBs.

**Keywords:** Lean Six Sigma, LSS, ISM, Fuzzy MICMAC

## 1. INTRODUCTION

Lean is about mastering the resources in accordance with the customer's needs and to reduce needless waste. The Lean concept was presented on a bigger scale by Toyota in 1950, but not branded lean manufacturing until the now famous book about the automobile appeared in 1990 (Womack, Jones, & Roos, 1990). Lean principles are fundamentally customer value driven, which makes them suitable for many manufacturing and distribution sites (Näslund, 2008; Snee & Hoerl, 2007). Motorola was the first company to instigate a Six Sigma method in the mid-1980s (Nave, 2002). Six Sigma is a business operation that allows companies to significantly advance their outcome by designing and monitoring daily business needs in ways that diminish waste and resources while escalating customer satisfaction. The Lean Six Sigma (LSS) concept can help organizations to enhance the operational efficiency, by uniting the benefit of lean and Six Sigma (Michael, Rowlands, & Kastle, 2004; Snee, 2010). While lean does not acquire the tools to lessen disparity and offer statistical control and Six Sigma does not endeavour to build up a linkage between quality and speed, the purpose of the combined tool LSS provides the valuable solution to increase efficiency and better quality in the industries. The benefits of combining lean and Six Sigma are modernize process stream to decrease complexity, reduce downtime, condense cycle period and lessen waste, get better product quality, attain constancy in product delivery, condense process and product expenses, reduce process disparity to reduce waste such as the waste of defective products, improve process control to maintain stable and expected processes (Antony, Kumar, & Madu, 2005; Antony,

Setijono, & Dahlgaard, 2016; De Koning, Does, & Bisgaard, 2008; Näslund, 2008).

However, regardless of these significant advantages, organizations keep on encountering an obstruction which ruins them from effective LSS implementing. These barriers/ obstruction are known as LSSBs. They exist inside (intra-firm) and outside the organization (inter-firm). Many studies focus on identification of these LSS barriers. Organization need to overcome these barriers hence can effectively implement LSS without many efforts. But only identification of these LSSBs is not enough, identification of the interrelationship among various LSSBs and identify the most driving barriers is requires for successful LSS implementation because these barriers are not only effect the LSS implementation but also effects on one- another. So in this study to obtain the interrelationship among identified LSSBs the interpretive structural modelling (ISM) and to clusters these LSSBs accordance to drive- dependency relationship fuzzy MICMAC (Matrix of Cross-Impact Multiplications Applied to Classification) analysis has use.

The structure of this study is as: In section 2 the details of literature review is provided. The application of combine ISM+MICMAC analysis is presented in Section 3. Finally the discussion and concluding remarks are presented in Section 4 and Section 5.

## 2. LITERATURE REVIEW

From vast LSS literature, initially we have identified total twenty-three LSS implementation barriers; we include opinions of industry practitioners and academic experts for identifying the most vital LSS barriers. After performing

two iterations of merging and removing those barriers have the same meaning. We finalize ten most signification barriers of LSS implementation. Dave, Muruges, & Devadasan, (2015) presented the literature review on LSS and identified the most common challenges in the implementation of LSS. The LSS implementation attempt in Indian healthcare sector has been presented by Bhat, Gijo, & Jnanesh, (2014), in the study, the authors presented the various challenges they face during LSS implementation. Antony, Krishan, Cullen, & Kumar (2012) have identified and present the challenges, barriers, success factors, tools/techniques of LSS for higher education institutions (HEIs). Psychogios, Atanasovski, & Tsironis (2012) investigate various issues related to the application of LSS in a service industry. Details of identified barriers are provided in Table I.

### 3. ISM AND FUZZY MICMAC METHODOLOGY AND MODEL DEVELOPMENT

Interpretive Structural Modeling (ISM) method was introduced by J.Warfield in 1974 to identify the relationship

among specific variables related to a complex problem or issue (Warfield, 1974). Manual methods are generally not clear when we have large numbers of variables and it becomes difficult to explain the interaction and inter-relationships among variables. ISM gives a clear understanding of all the variables and their relationship with other variables. So, when we have a complex issue and a systematic and logical thinking approach is required, then ISM is used. ISM is an interactive learning process in which a set of different and directly related variables of interest are arranged into a systematic hierarchical model known as a structural model for the solution of a complex problem and also provides a graphical representation based on the driving and dependent nature of the elements. Matriced Impacts Croisés Multiplication Appliquée á un Classement (MICMAC) developed by Duperrin & Godet (1973). The MICMAC analysis helps to obtain the dependencies existing among the LSSBs. And to overcome the limitation of conventional MICMAC analysis, in this study Fuzzy MICMAC analysis have been utilized.

**TABLE 1: Identified LSSBs**

LSSBs No	LSSB	Literature support
1	Lack of management commitment	(Antony et al., 2012; Dave et al., 2015; Kumar, Kumar, & Haleem, 2015; Leseure, Hudson-Smith, Delgado, Ferreira, & Castelo Branco, 2010)
2	lack of knowledge about the methodology and lack of resources	(Bhat et al., 2014; Hess & Benjamin, 2015)
3	lack of knowledge concerning the LSS framework and project requirements	(Psychogios & Tsironis, 2012; Thomas, Barton, & Chuke-Okafor, 2008)
4	Lack of training	(Antony et al., 2012; Psychogios et al., 2012)
5	Culture which is not compatible for implementing LSS	(Antony et al., 2012; Lertwattanapongchai & William Swierczek, 2014; Psychogios et al., 2012)
6	Insufficient funds and improper fund allocation	(Psychogios et al., 2012; Thomas et al., 2008)
7	Lack of IT implementation and effective communication system	(Franchetti & Barnala, 2013; Kumar, Luthra, Govindan, Kumar, & Haleem, 2016)
8	Poor meeting of customer expectation	(Kumar et al., 2016; Psychogios et al., 2012; Snee, 2010)
9	Lack of project planning and management	(Thomas et al., 2008; van den Bos, Kemper, & de Waal, 2014)
10	Absence or insufficient integrated communication and cooperation between firm and their supplier	(Kumar et al., 2015; Psychogios & Tsironis, 2012)

#### 3.1 Interpretive Structural Modelling (ISM)

The various steps, which lead to the development of ISM model, are illustrated as given below.

- 1. Identification of variables:** The various barriers hinder the LSS implementation is identified from literature review, brain-storming and expert opinion.

The identified LSSBs and their appropriate codes are given. And details of literature support of these LSS barriers is provided in Table I.

- 2. Contextual relationship:** From the LSSBs identified in step 1, a contextual relationship is determined. The contextual relationship between the various LSSBs is established with help of expert opinion and brain

storming. This is useful for examining the pairs of variables. After the establishment of the contextual relationship, a structural self-interaction matrix (SSIM) is prepared based on the contextual relationship among variables. This SSIM represent the pair-wise relationship between each available variable. In SSIM the relationship between various variables is represented in the form of V, A, X and O.

Table II shows the self-interaction matrix (SSIM).

Where, V – for the relation from variable i to variable j.

A – for the relation from variable j to variable i.

X – for both direction relation from variable i to variable j and variable j to variable i.

O – If there is no direct relationship between variables i and j.

**TABLE 2: Structural self-interaction matrix**

LSSB no	10	9	8	7	6	5	4	3	2
1	V	V	V	V	V	V	V	V	V
2	V	X	V	V	A	X	X	A	
3	O	V	V	V	O	V	V		
4	V	X	V	V	A	X			
5	V	X	V	O	A				
6	V	V	V	V					
7	X	A	V						
8	A	A							
9	V								

3. **Initial Reachability Matrix (IRM):** Obtained SSIM is converted into binary matrix known as initial reachability matrix. This conversion is made by substituting symbols V, A, X and O by digit 0 and 1.

The substituting of symbols is carried out as per following rules.

If the (i, j) entry in the SSIM is V, then the (i, j) entry in the reachability matrix becomes 1 and the (j, i) entry becomes 0.

If the (i, j) entry in the SSIM is A, then the (i, j) entry in the reachability matrix becomes 0 and the (j, i) entry becomes 1.

If the (i, j) entry in the SSIM is X, then the (i, j) entry

in the reachability matrix becomes 1 and the (j, i) entry also becomes 1.

If the (i, j) entry in the SSIM is O, then the (i, j) entry in the reachability matrix becomes 0 and the (j, i) entry also becomes 0.

Then initial reachability matrix is checked for transitivity for development of final reachability matrix (FRM). This transitivity of the contextual relationship is based on the assumption that if variable A is related to variable B and variable B is related to variable C, then variable A is necessarily related to variable C. The initial reachability matrix is shown in Table III and the final reachability matrix is shown in Table IV.

**TABLE 3: Initial reachability matrix**

LSSB no	1	2	3	4	5	6	7	8	9	10
1	1	1	1	1	1	1	1	1	1	1
2	0	1	0	1	1	0	1	1	1	1
3	0	1	1	0	1	0	1	1	1	0
4	0	1	0	1	1	0	1	1	1	1
5	0	1	0	1	1	0	0	1	1	1
6	0	1	0	1	1	1	1	0	1	1
7	0	0	0	0	0	0	1	1	0	1
8	0	0	0	0	0	0	0	1	0	0
9	0	1	0	1	1	0	1	1	1	1

3	0	1	1	0	1	0	1	1	1	1*
4	0	1	0	1	1	0	1	1	1	1
5	0	1	0	1	1	0	1*	1	1	1
6	0	1	0	1	1	1	1	0	1	1
7	0	0	0	0	0	0	1	1	0	1
8	0	0	0	0	0	0	0	1	0	0
9	0	1	0	1	1	0	1	1	1	1
10	0	0	0	0	0	0	1	1	0	1

4. **Level Partitions:** From the final reachability matrix, the reachability set and antecedent set for each LSSBs are found. The reachability set includes LSSBs itself and other LSSBs which may help to achieve. And the antecedent consist LSSBs and other LSSBs which may help in achieving it. Then, the intersection of these sets is identified for all available LSSBs. For LSSBs for which reachability and intersection sets are same is the top level LSSBs. Then, the same procedure is repeated until each LSSBs are identified for their respective levels. The level partition of each LSSBs is given in Table V.

**TABLE 5: Level of LSSBs**

LSSB no	Reachability set	Antecedent set	Intersection set	Level
1	1	1	1	V

5. **Formation of ISM model:** To build ISM first the FRM is converted into the canonical matrix format by rearranging each LSSB according to their level. Then, the directed graph is drawn by means of nodes and arrow. This resultant directed graph also known as diagraph is converted into ISM by replacing nodes with appropriate statement of LSSBs. Then nodes are replaced by the statements of the LSSBs. This gives final ISM network. The diagraph is shown in Fig.1 and the final ISM model is shown in Fig. 2.

### 3.2 Fuzzy MICMAC methodology

For developing ISM model, the relationship between two LSSBs is denoted by 0 and 1. If there is no relationship between them then it is denoted by 0 and if there is the

relationship among them then it is denoted by 1. The relationship between LSSBs cannot be always same. Some relation may be strong, some may be very strong. To overcome this drawback of ISM model, fuzzy MICMAC analysis is used. Various steps for Fuzzy MICMAC are as below.

1. To obtain binary relationship matrix for Fuzzy MICMAC, the diagonal entries of FRM are converted to zero. Derived binary direct relationship matrix (BDRM) is shown in Table VI.
2. **Fuzzy Direct Reachability Matrix (FDRM):** Conventional MICMAC approach considers the only binary type of relationships. In this study Fuzzy approach is used to increase the sensitivity of

MICMAC. In Fuzzy MICMAC, an additional input of possible reachability is used. The possible reachability for variables is given in Table VII. Value With help of expert opinion the possible reachability for variables

is included in BDRM and fuzzy Direct Reachability Matrix (FDRM) is developed. The FDRM is shown in Table VIII.

3. **Fuzzy MICMAC Stabilized Matrix:** The FDRM is multiplied until the hierarchies of the driver and dependent power are stabilized. This multiplication follows the rule of fuzzy multiplication. Fuzzy multiplication is basically a generation of a Boolean

matrix Gorane and Kant, (2012). According to fuzzy set theory, when two matrices are multiplied then the product matrix is also a fuzzy matrix. This Fuzzy multiplication follows the below rule: Fuzzy multiplication.

$C = (A*B) = \max K [\min (a_{ik}, b_{kj})]$ , Where,  $A = [a_{ik}]$  and  $B = [b_{kj}]$

A stabilized matrix is shown in Table IX. The driving power of the LSSBs in fuzzy MICMAC is derived by addition of the entries of possible interaction in rows, and the dependent power of the LSSBs is determined by addition of the entries of possible interaction in columns.

**4. Categorization of LSSBs:** All LSSBs have been classified, based on their driving power and dependence power, into four categories as autonomous LSSBs, dependent LSSBs, linkages LSSBs, and driver LSSBs. In this classification of LSSBs, the first cluster consists autonomous LSSBs, which have weak driving power and also have weak dependence power.

Second cluster consist dependent LSSBs, which have strong dependence power and weak driving power. The third cluster consist linkage LSSBs, which have strong driving power and also have strong dependence power. The forth cluster consist driver LSSBs which have strong driving power and weak dependence power. Fig.3 shows the Cluster of LSSBs.

Fig. 3. Cluster of LSSBs

#### 4. RESULT AND DISCUSSION

From Fig. 2 it is shown that ISM network consist five levels. 'Poor meeting of customer expectation' is top level LSSB. On the second level of ISM hierarchy 'Lack of IT implementation and effective communication system' and 'Absence or insufficient integrated communication and cooperation between the firm and their supplier' are there. While 'Lack of knowledge about the methodology and lack of resources', 'Lack of training', 'Culture which is not compatible for implementing LSS' and 'Lack of project planning and management' are at level three. On level four two LSSBs are there namely 'Lack of knowledge concerning the LSS framework and project requirements' and 'Insufficient funds and improper fund allocation'. And 'Lack of management commitment' is last level LSSB.

From Fuzzy MICMAC analysis, all LSSBs can be classified based on driving-dependence power.

##### 4.1 Autonomous LSSBs

From a cluster of LSSBs there are no autonomous LSSBs in this system. Autonomous LSSBs have weak driving power and also have weak dependence power. The autonomous LSSBs are relatively disconnected from the system, hence any change in autonomous LSSBs do not have much more effect on ISM network.

##### 4.2 Dependent LSSBs

From cluster of LSSB, lack of knowledge about the methodology and lack of resources, culture which is not compatible for implementing LSS, lack of IT implementation and effective communication system, poor

meeting of customer expectation, lack of project planning and management and absence or insufficient integrated communication and cooperation between firm and their supplier are fall under cluster of dependent LSSB. These LSSBs have weak driving power and strong dependence power. That means the change in dependence LSSBs have does not much more effect on ISM, and change in driver LSSBs have much more effect on dependence LSSB. They are seen at the top level of the ISM hierarchy. Their strong dependence power indicates that they require all other LSSBs to overcome their effect.

##### 4.3 Linkage LSSBs

There is no linkage LSSBs is available in this system. Linkage LSSBs have high driving power and also have high dependence power. That means a change in linkage LSSBs have the effect on other LSSBs and also have the effect on themselves. They are unstable in nature. Linkage LSSBs may affect the system either in a positive or negative way.

##### 4.4 Driver LSSBs

From above cluster of LSSBs following LSSBs are the driver LSSBs for this system: lack of management commitment, lack of knowledge concerning the LSS framework and project requirements, lack of training and insufficient funds and improper fund allocation. They have strong dependence power means a change in these driving LSSBs has significant effect on ISM network. Driving LSSBs are key variables to controlling the ISM hierarchy. In ISM network they are at the bottom level of ISM hierarchy.

## 5. CONCLUSION

From an extensive literature review and a discussion with the expert team, we have identified total twenty-three LSS implementation barriers out of which ten LSSBs is finalised for this study. The purpose of this study is to understand the interactions among these LSSBs using ISM and fuzzy MICMAC analysis. The major contribution of this paper lies in the development of contextual relationships among identified LSSBs through a systematic framework. The present paper provides an ISM-fuzzy MICMAC-based model to understand the relationships among identified LSSBs. ISM methodology is used to develop a map of the complex relationships among various LSSBs. Through the ISM-based hierarchical model, it is observed that the poor meeting of customer expectation exists at the top level in the ISM hierarchy. Lack of management commitment is at the base of this model. Policy-makers should give appreciable consideration to the LSSBs that exist at the base of the hierarchy. The results of the ISM are used as an input to the fuzzy MICMAC analysis to identify the driving power and dependence of LSSBs. The organization should give more focus towards to overcome the driving LSSBs so as to manage the dependent LSSBs for a successful implementation of LSS.

# Study of Different Parameter in Advance Machining Process

Shyam K. Fardale

Datta Meghe Institute of Engineering Technology and Research, Wardha, Maharashtra, India

---

**Abstract:** Since beginning of the human progress, people have evolved tools and energy sources to power these tools to meet the requirements for making the life easier and enjoyable. In twentieth century products were made from the most durable and consequently, the most unconventional methods. In an effort to meet the manufacturing challenges created by these methods, tools have now evolved to include materials such as alloy steel, carbide, diamond and ceramics. The greatly improved thermal, chemical, and mechanical properties of the new engineering materials made it impossible to machine them using the traditional machining processes of cutting and abrasion.

In modern machining practice, harder, stronger, and tougher materials that are more difficult to cut are frequently used. More attention is, therefore, directed toward machining processes where the mechanical properties of the work piece material are not imposing any limits on the material removal process. These methods play a considerable role in the aircraft, automobile, tool, die, and mold making industries.

During the last 55 years, over 20 different non-traditional manufacturing processes have been invented and successfully implemented into production. The non-conventional manufacturing processes are not affected by hardness, toughness or brittleness of material and can produce any intricate shape on any work piece material by suitable control over the various physical parameters of the processes.

---

## 1. REVIEW OF LITERATURE

Abrasive water jet cutting is an extended version of water jet cutting; in which the water jet contains abrasive particles such as silicon carbide or aluminium oxide in order to increase the material removal rate above that of water jet machining. Almost any type of material ranging

From hard brittle materials such as ceramics, metals and glass to extremely soft materials such as foam and rubbers can be cut by abrasive water jet cutting. The narrow cutting stream and computer controlled movement enables this process to produce parts accurately and efficiently. This machining process is especially ideal for cutting materials that cannot be cut by laser or thermal cut. Metallic, non-metallic and advanced composite materials of various thicknesses can be cut by this process. This process is particularly suitable for heat sensitive materials that cannot be machined by processes that produce heat while machining.

**Dr. N. Mohana Sundara Raju** With reference to "Analysis of surface roughness in abrasive water jet cutting of cast iron" Surface roughness is one of the most important criteria, which help us determine how Rough a work piece material is machined. By analyzing the experimental data of the selected material, it has been found that the optimum selection of the four basic Parameters, i.e., water pressure, abrasive mass flow rate, nozzle traverse speed and Nozzle

standoff distance are very important on controlling the process outputs such as surface roughness.

**Derzija Begic-Hajdarevic et al.** studied the effects of material thickness, traverse speed and abrasive mass flow rate during abrasive water jet cutting of aluminum on surface roughness. They analyzed that traverse speed has great effect on the surface roughness at the bottom of the cut and the correlation between the surface roughness and other abrasive water jet cutting variables.

**Introduction: -** There are three major areas classified under advanced machining processes. These streams are mechanical, thermo-electrical and electro-chemical. One of such important mechanical advanced machining process is Abrasive Water Jet (AWJ) machining. The abrasive water jet machining process does not generate any heat because of which there are not heat affected zones and residual stresses during the surface generation process. The inherent characteristic of the process is that it is non-contact and dynamic cutting process. The other notable benefits include thin kerf width,

Negligible heat affected zone, and flexibility during material removal. Various classes of Abrasives are usually applied during AWJ machining like garnet, olivine, aluminum oxide (Al₂O₃), silica-sand, glass bead, silicon carbide (SiC), zirconium, etc. There are several advantages of abrasive water jet machining process such as no thermal alterations; flexibility in machining, larger applicability

besides very small cutting forces. There are several distinguished advantages of AWJ technique. It is less sensitive to material properties and hence does not cause chatter, has no thermal effects, imposes minimal stresses on the work piece, and has high machining versatility and flexibility. It has been always challenging to incorporate constricted

Tolerances on the components and parts machined using the process. In addition to the materials

Having superior properties, the machining quality can also be extended for the applications

The apparatus of water jet machining consists of the following components:

- 1) **Reservoir:** It is used for storing water that is to be used in the machining operation
- 2) **Pump:** It pumps the water from the reservoir. High pressure intensifier pumps are used to pressurize the water as high as 55, 000 psi. For the abrasive water jet, the operating pressure ranges from 31, 000 to 37, 000 psi. At this high pressure the flow rate of the water is reduced greatly.
- 3) **Intensifier:** It is connected to the pump. It pressurizes the water acquired from the pump to a desired level.
- 4) **Accumulator:** It is used for temporarily storing the pressurized water. It is connected to the flow regulator through a control valve.
- 5) **Control Valve:** It controls the direction and pressure of pressurized water that is to be supplied to the nozzle.
- 6) **Flow regulator:** It is used to regulate the flow of water.
- 7) **Nozzle:** It renders the pressurized water as a water jet at high velocity. Once the water is pressurized, it is forced through a sapphire nozzle which is composed of the natural sapphire stone due to the strength of the stone. The diameter of the nozzle can be varied depending on the application for which the water jet is being used. A damaged nozzle leads to poor cohesion of the stream, thereby reducing the cutting ability greatly. The nozzle typically lasts 100 to 200 hours before it needs to be replaced.
- 8) **Mixing Tube:** The stream of water which emerges from the nozzle is then mixed with the abrasive. This takes place in the mixing tube, which is usually constructed out of tungsten-carbide. Wear of the mixing tube, due to the abrasive, is a problem and it needs frequent replacement. When the tube becomes

worn, the jet no longer is cohesive and loses power and cutting ability rapidly.

- 9) **Catchers:** After the cut has been made, the water abrasive material is collected in a catcher. In a field situation there are still problems catching the waste material. Often catchers need to be custom designed for a specific job

AWJC process is significantly affected by the Process tuning parameters .There are numerous associated parameters in this technique, among which are as follows.

1. Abrasive mass flow rate
  2. Nozzle tip distance
  3. Gas Pressure
  4. Velocity of abrasive particles
  5. Mixing ratio
  6. Abrasive grain size
- 1) **Abrasive mass flow rate:** - Mass flow rate of the abrasive particles is a major process parameter that influences the metal removal rate in abrasive jet machining. In AJM, mass flow rate of the gas (or air) in abrasive jet is inversely proportional to the mass flow rate of the abrasive particles. Due to this fact, when continuously increasing the abrasive mass flow rate, Metal Removal Rate (MRR) first increases to an optimum value (because of increase in number of abrasive particles hitting the work piece) and then decreases. However, if the mixing ratio is kept constant, Metal Removal Rate (MRR) uniformly increases with increase in abrasive mass flow rate.
  - 2) **Nozzle tip distance:** Nozzle Tip Distance (NTD) is the gap provided between the nozzle tip and the work piece. Up to a certain limit, Metal Removal Rate (MRR) increases with increase in nozzle tip distance. After that limit, MRR remains constant to some extent and then decreases. In addition to metal removal rate, nozzle tip distance influences the shape and diameter of cut. For optimal performance, a nozzle tip distance of 0.25 to 0.75 mm is provided.
  - 3) **Gas Pressure:** Air or gas pressure has a direct impact on metal removal rate. In abrasive jet machining, metal removal rate is directly proportional to air or gas pressure.
  - 4) **Velocity of abrasive particles:** Whenever the velocity of abrasive particles is increased, the speed at which the abrasive particles hit the work piece is increased. Because of this reason, in abrasive jet machining, metal removal rate increases with increase in velocity of abrasive particles.

- 5) **Mixing ratio:** Mixing ratio is a ratio that determines the quality of the air-abrasive mixture in Abrasive Jet Machining (AJM). It is the ratio between the mass flow rate of abrasive particles and the mass flow rate of air (or gas). When mixing ratio is increased continuously, metal removal rate first increases to some extent and then decreases.
- 6) **Abrasive grain size:** Size of the abrasive particle determines the speed at which metal is removed.

**Experimental setup:** - Considering all parameters of Water jet machining we focus on abrasive material in terms of Mixing ratio and size-type of abrasive practical. Based on the application situations, work material consider Stainless Steel Type 316.

#### Work Material

Stainless steel type 316 is part of a family of stainless steel alloys (301, 302, 303, 304, 316, 347). The 316 family is a group of austenitic stainlesssteels with superior corrosion resistance to 304 stainless steel. This alloy is suitable for welding because it has a carbon content lower than 301 to 303 series alloys to avoid carbide precipitation in welding applications.

Stainless Steel 316		
Nominal Composition in Percentage:		
Sr No	Element Content	Percentage
1	Ni	12
2	Cr	17
3	Mo	2.5
4	Fe	Balance
5	Si	1
6	Mn	2
7	Cr	0.08
8	P	0.045
9	S	0.03

#### Parametric Study

Abrasive practical: - Geometry, hardness and size can be considered the most important characteristics affecting the wear rate caused by abrasive particles. The combined effect of these characteristics on wear has not yet been modeled as a whole. One particular model, proposed by Rabinowicz et al. (1961), involves a single particle being considered as a pointed tool, so that the effect of the geometry can be determined.

Fig. 1. Conical abrasive particle cutting a groove of depth  $p$ , and sliding for a distance  $\Delta l$  to produce a wear volume  $V$  (Rabinowicz et al., 1961).

The wear rate is expressed as follows:

$$\frac{dV}{dl} = \frac{\tan \theta}{H} W$$

- 1) **Tan  $\theta$ :** - is the average tangents of all roughness angles of the abrasive particles,
- 2) **H** is the hardness of bearing surface
- 3) **W** is the total load.

In this case the particle is considered to be a solid body that neither degrades nor changes Size and whose properties remain constant throughout the whole wear process. This Hypothesis is not verified, especially for those situations where the hardness of abrasive is Lower than the abraded material. This situation led to small wear rates, and it is usually classified as mild wear (Gates, 1998). The fragmentation of particles depends on their

Fracture toughness, and it is possible to verify in the literature data that the higher the hardness, the higher the fracture toughness (Fig.) Therefore, for softer abrasives the breakage is easier.

## 2. RESULT AND DISCUSSION

Experiment was conducted to analysis the parameter, some result was concluded on given experimental setup. Value of set variable are as follow Water/jet Pressure 100Mp, Jet travel speed was 1000 to 2000 mm/Sec, Stand-off distance of 2mm.

### 1) Effect of standoff distance on depth of cut :-

The depth of cut was measure with changing standoff distance for Speed at 1500mm/min and 2000 mm/min.

Test For Jet speed 1500 mm/min		Test For Jet speed 2000 mm/min	
Stand off Distance mm	Depth of cut, mm.	Stand off Distance mm	Depth of cut, mm.
2	0.12	2	0.2
3	0.19	3	0.23
4	0.25	4	0.32
5	0.31	5	0.39

Effect were seen where standoff distance increases also increases the depth of cut.

**Fig. 2. The effect of stand-off distance on depth of cut**

- 2) **Effect of Travel speed on depth of cut:** -Test were conducted for different speed of jet at abrasive flow rate 100 g/min and 150 g/min depth of cut was calculated. Are shown in table.

Abrasive flow rates of 100 g/min.		Abrasive flow rates of 150 g/min.	
Traverse speed mm/min	Depth of cut, mm.	Traverse speed mm/min	Depth of cut, mm.
1000	0.8	1000	0.6
1100	0.76	1100	0.57
1200	0.72	1200	0.53
1300	0.66	1300	0.51
1400	0.62	1400	0.48
1500	0.6	1500	0.42
1600	0.58	1600	0.3
1700	0.55	1700	0.28
1800	0.52	1800	0.25
1900	0.49	1900	0.24
2000	0.45	2000	0.22

Fig. 3. The effect of Travel speed on depth of cut

- 3) **Effect of abrasive flow rate on depth of cut :-**Test were conducted on abrasive flow rate 100gm/min to 150 gm/min and some result were calculated on two different jet speed at 1500 mm/min and 2000 mm/min.Relation between the variable are shown in fig-

Test For Jet speed 1500 mm/min		Test For Jet speed 2000 mm/min	
Abrasive flow rategm/min	Depth of cut, mm.	Abrasive flow rate gm/min	Depth of cut, mm.
100	0.12	100	0.2
110	0.19	110	0.23
120	0.25	120	0.32
130	0.31	130	0.39
140	0.36	140	0.43
150	0.42	150	0.48

Fig. 4. The effect of abrasive flow rate on depth of cut

### 1) Effect of standoff distance on Material Removing Rate

Test was conducted on different standoff distance changing from 2, 3, 4, 5mm and check Material removal rate are as shown in table

Test For Ject speed 1500 mm/min		Test For Ject speed 2000 mm/min	
Stand off Distance mm	Material removal rate mm3/min	Stand off Distance mm	Material removal rate mm3/min
2	82	2	90
3	84	3	92
4	83	4	91
5	86	5	93

Fig. 5. Effect of standoff distance on Material Removing Rate.

### 2) Effect of Travel Speed on Material Removing Rate

Test were conducted on two type of abrasive flow rate 100 g/min and 150 g/min it was found that traverse speed increases Material removal rate is decreases as shown in table

Abrasive flow rates of 100 g/min.			Abrasive flow rates of 150 g/min.		
Traverse speed mm/min	Material removal rate mm3/min		Traverse speed mm/min	Material removal rate mm3/min	
1000	112		1000	156	
1100	107		1100	148	
1200	96		1200	143	
1300	85		1300	137	
1400	73		1400	122

1600	62		1600	102	
1700	58		1700	96	
1800	53		1800	88	
1900	52		1900	76	
2000	51		2000	68	

Fig. 6. Effect of Travel Speed on Material Removing Rate.

### 3) Effect of abrasive flow rate on Metal Removing Rate:-

Test were conducted to find out the effect of abrasive flow rate on material removing rate, with two speed at 1500 mm/min and 2000 mm/min table show the details of same.

Test For Ject speed 1500 mm/min		Test For Ject speed 2000 mm/min	
Abrasive flow rate gm/min	Material removal rate mm3/min	Abrasive flow rate gm/min	Material removal rate mm3/min
100	80	100	92
110	92	110	96
120	103	120	110
130	112	130	123
140	123	140	134
150	132	150	141

Fig. 7. Effect of Travel Speed on Material Removing Rate

### 3. CONCLUSION

To achieve this objective a series of tests were conducted using an industrial AWJ machine to generate rectangular Slot in steel alloy as a specimen. The considered process parameters are depth of cut, and metal removal rate. The considered process variables are traverse speed, jet pressure, abrasive flow rate and stand-off distance. The summary of the results is shown in Table

Summary of the effects of AWJ process variables on process parameters			
Process variable	Process variable range	Effect of variable increase on process parameters	
		Depth of cut	MRR
Traverse speed	From 1000 to 2000 mm/min	Decrease	Decrease
Abrasive flow rate	From 100 to 150 g/min.	Increase	Increase
Stand-off distance	2, 3, 4, 5 mm	No effect	No effect

The above table shows that some process erratic has no effect on process restriction this yields to discard these variables in any process control operation, In addition, this result has an important effect on selecting or designing AWJ machines for slotting Operations. Since the stand-off distance has no noticeable effect on process parameters, it is better to select a longer value to prevent the nozzle front from damaging by the reflection of the water stream and abrasive.

⁴Department of Mechanical Engineering, KDK College of Engineering, Nagpur, Maharashtra, India

**Abstract:** The aim of this paper is to identify the different types of defects occur in SMAW (Shielded Metal Arc Welding) welding process. A literature review is made to find the SMAW process parameter. SMAW is one of the metal joining processes. It is widely used process for fabrication, and industrial purpose. Performance of welding is depending on quality of welding. It is mainly affected by the defect in weld profile. Defects occur in weld profile are porosity, holes, incomplete penetration, incomplete fusion, crack etc. The identified welding process parameters are welding current, arc voltage, electrode angle, welding speed, and wind velocity. For doing the literature review seven papers from reputed journals and the relevant workshops review are used.

**Keywords:** SMAW, Welding parameters, Defects, literature review.

## 1. INTRODUCTION

The Shielded Metal Arc Welding (SMAW) is very flexible, portable, versatile, and having low cost process of metal joining by fusion of material. The working process of SMAW is very simple than other welding process. The arc is created between electrode tip and work piece when current is supply. Which causes heat generation about 6500°F due to this metal is melted and metallurgical bond is formed. The SMAW process is very much useful to join mild steel material.

**Fig. 1. Working of SMAW process**

The strong joint of mild steel plate is done by the SMAW process (S.M.Ravikumar, Dr.P.Vijian, 2014). Among all the other process of welding SMAW is very versatile and

important because having advantage of having compact and small setup of equipment so it is easily shifted. The cost of equipment of SMAW process is very less. SMAW is the manual welding process which is also called as stick or cover electrode welding process because the consumable electrode used in process having the cover of flux powder around it (S.M.Ravikumar, Dr.P.Vijian, 2014). Other than casting, riveting, friction welding SMAW is more economical and much faster process of joining metals. This process find almost 50% of total application in industries because it is very flexible having a wide variety of electrodes. It makes possible to weld number of alloys. To get the desired weld it is essential to know the interrelationship between parameter. The weld bead geometry is mainly deciding the quality of weld. It is achieve by considering best setting of input parameter.

The performance of welding process is mainly depending on the values of their parameter with respect to specification of material. It affects the strength, repairing cost and productivity. Mainly there are two type of welding parameter controllable and uncontrollable parameter of welding. Welding current, Arc voltage, electrode to work piece angle, Root gap, weld metal deposition, weld speed are the controllable parameter of SMAW. Weld bead dimension, Heat affected zone, weld penetration are the uncontrollable parameter of SMAW (Raghavendra N and Dileep Kumar, 2015). The welding process parameter setting is mainly affecting the quality of weld and the type of defect which occur in welding are incomplete fission, crack, weld bead geometry, incomplete penetration, holes, porosity. There are various method to identify the defects in welding which are destructive and non-destructive method of inspection are radiographic inspection, ultrasonic

inspection, vision inspection, magnetic detection and online computer vision inspection of weld bead by using sensor (Gang Wang, T. Warren Liao, 2001; S.M. Tabatabaeipour, F. Honarvar, 2010).

## 2. LITRATURE REVIEW

### 2.1 From journals

Raghavendra N and Dileep Kumar (2015) discuss to optimize the process for joining of pipe so that there is continuous and leak proof joint by the SMAW process. The experiments were done on the steel pipes having diameter of 48mm and the wall thickness 3mm. The Taguchi method is applied to optimize the process by using different parameters of SMAW process are welding current, welding speed, root gap and position of electrode base in the range of 80-100 amp, 4-6 rpm, 30-60 deg, 0-1.5mm respectively. The output result i.e. leakage of joint is measured by hydraulic hand pump of capacity 400 bars, at 30 bars. After the experiment it is found that the leakage in pipes when welding current at 90 amp and all three parameter are at low level. Also the leakage is present in pipe when the angle of electrode is at highest level i.e. at 90deg. So the two factor welding current and the electrode angle are more significant for leak proof joint of pipe.

S. M.Ravikumar, Dr.P.Vijian (2014) work on improving the quality of weld bead geometry of the SMAW process. The study of process is done on the mild steel plate IS2062 having dimensions 100mm×50mm×6mm and E6013 electrode having 3.5mm diameter. To optimize the process they uses Taguchi DOE with L9 OA. The various input parameter used in the experiment are welding current, welding speed and additional parameter wind velocity. The ranges of parameter used are 100-140 amp, 2-4mm/s, 3-7m/s respectively The output parameter measured are the dimensions of weld bead profile by process of etching, after completion of welding with the specification of OA decide. Then cut the sample at the midpoint such that the weld pool is perpendicular to the cut. Then the specimen are prepared by metallurgical polishing and etching it with 5% nital solution after this the weld bead profile is measured by the optical microscope (10X) in the form of width(W), penetration(P), reinforcement(R).they uses the Greay relation analysis to find the optimal solution which are welding current(140 amp), welding speed (4mm/s), and wind velocity(7m/s) and the significance of parameter in process are welding current(47.71%), welding speed (30.40%), and wind velocity(19.54).

Fig. 2. Weld profile

R.P. Singh, R.C. Gupta and S.C. Sarkar(2012) discuss about the effect of magnetic field on with different parameter on penetration the experiment was done on the mild steel plate having dimension of 150 mmx50 mmx5 mm butt joint, steel electrodes of 3.15 mm diameter by using SMAW process. The different parameters and their ranges used are welding current (90-110Amp), arc voltage (20-24V), welding speed (40-80mm/min), and external

magnetic field (0-80Gauss) and to measure the output parameter by etching the cut part, dipped in mixture of 2% nitric acid and 98% ethyl alcohol solution and then measured the dimension. The analysis was done with the help of artificial neural network. The magnetic field decrease the depth of penetration. The more penetration is at 100 A current, 22 V voltage, 40 Gauss magnetic field and 40mm/min welding speed.

**Fig. 3. Distribution of welding defects in the test data**

Gang Wang, T. Warren Liao(2001) discuss about the identification of different defects of welding by the radiographic image processing. The three main step in the radiographic testing are digital image processing, feature extraction, and pattern classification. These techniques differentiate the defect from pattern by changing the contrast. Dimensions are measured by measuring distance from centre, radius, major axis, width etc. The X-ray film strip used is about 3.5 in. wide and 17 in long, digitized about 70 $\mu$ m. The object is digitized by the NDT SCAN II digitizer. The different types of defect measured by the author are crack, gas hole, lack of fusion, lack of penetration, porosity. How much this defects are present is shown in graph.

S.M. Tabatabaeipour, F. Honarvar(2010) do their work to identify different behaviour of the base material (AISI 316L) welds of two process GTAW and SMAW by using the ultrasonic testing. The dimensions of the base material are thickness of base material, root face, and root gap were 25, 2, and 2mm, respectively were selected. First the defect is measured by the X-ray radiography then the ultrasonic time-of-flight diffraction is applied on specimen 6MHz

longitudinal angle beam probes is used in the experiment. Ultrasonic waves are applied from various direction and longitudinal wave mode, Shear wave mode are measured. It is found that the defect of SMAW is clearly observed in B-scan image but the defect of GTAW is not, because of the grain size.

J. Edwin Raja Dhasa, S. Kumanan(2011) discuss about the weld quality which is describe by the weld bead geometry, deposition rate and hardness by submerge arc welding. These parameter are affected by the input parameter which are consider by author are welding current, welding speed, arc voltage and electrode stickout. To get the decided objective Taguchi and nonconventional technique such as genetic algorithm (GA) and particle swarm optimization (PSO) are used. The experiment was done on 500mm $\times$ 50 mm $\times$ 6 mm mild steel plate by using the ER70S-6 copper coated electrode. I/P parameter used in the range of welding current (360-390A), welding speed(400-420mm/min), arc voltage(25-26V) and electrode stickout(19-25mm).it is found that the optimization process PSO does not give any model of optimization. Therefore this process is best welding shop floor environment.

S. Kumanan, J. Edwin Raja Das(2007) do their work to identify the weld quality by measuring the different weld bead dimension (bead width, bead reinforcement, depth of penetration and bead hardness, holes) of the SAW process, and optimize the welding parameter by using Taguchi DOE and regression analysis. The work is done on mild steel plate with 500mm $\times$  50mm $\times$  6mm with square butt joint and having 1mm root gap by using SAW process. The different working parameter used are welding current, arc voltage, welding speed, and electrode stickout in the range of 360-390 amp, 25-26 volt, 400-420 mm/min, 19-25mm respectively. The weld bead geometry is measured by cutting 10mm width samples, polish it and etched. Hardness is measured by Rockwell hardness.

#### Analysis of literature Review

#### 2.2 From Relevant Workshop

Durga Engineering Workshop at wadi near petrol pump, Nagpur. working on all sheet metal works making products

such as DP case, hopper of big rice mill, boxes of sheet metal and using the SMAW process for welding. The thickness of sheet they are using from 20-18 gauge. The

defects arises in welding are incomplete fusion, holes, porosity etc which giving bad appearance of product.

Shree Sitaram Engineering Workshop at bypass road, Ramtek it is a metal fabricating workshop. mainly produce Shutter, Grills, Ladder, Pipe gate, Windows, iron Doors. In joining of sheet due to improper welding parameters the problem of holes are seen in sheet welding because of excess heat generation causes melting of sheet. If sheet are joint with channel sheet melted fast therefore improper welding occur.

Rajesh Engineering Workshop at mandir road, Ramtek manufacturing the product such as Pipe gate, sintering

plate, windows, ladders, collapse gate, iron doors. They are using high voltage SMAW process to join the metals. The defect in weld are holes in pipe, incomplete penetration, incomplete fusion are found

Hannef welding workshop at super market, Ramtek mostly working on manufacturing of metal counters and pan shop. The welding is on angle having more thickness and sheet having less thickness. The sheet melted first due to more heat generation and which is not fuse with angle having more thickness therefore incomplete fusion type of defect is found. Welding thick material the heat generation is more and due to uneven cooling cracks and porosity type of defects are found.

**Fig. 4. Incomplete Fusion**

**Fig. 5. Holes**

**Fig. 6. Incomplete Penetration**

### 3. RESEARCH GAP

After studying above literature review (both journals and workshop), it is found that

1. There is no standard setting of welding parameters (Trial and error method is used)
2. Less work is done to weld mild steel sheets having less thickness
3. Input parameters like electrode angle, welding speed are not considered.
4. The problem of defects like porosity, spatter, wall fusion interface is not discussed with Taguchi and DOE approach.

The different types of defect occur in welding because of improper setting of welding parameter are porosity, incomplete fusions, holes, weld bead geometry, incomplete penetration, crack. These types of defect decrease the strength of product. To improve the strength it is require repairing the defect. The repairing cost is additional to the manufacturing cost of product. Also the defect causing bad appearance of product it decreases the selling price of product. The different parameters affecting the weld quality are welding current, arc voltage, welding speed, electrode angle etc.

### 4. CONCLUSSION

Less work is done to weld mild steel sheets having less thickness (less than 6mm). Input parameter such as electrode angle, welding current, arc voltage and welding speed is mainly affected the welding quality. Taguchi is the best tool of design of experiment to optimize the process. Weld quality is mainly depending on penetration, and fusion of parent material it is affected by welding current, arc voltage and welding speed. If welding current and arc voltage is maximum and welding speed is minimum gives the highest penetration and fusion of material.

### 5. FUTURE SCOPE

By using above literature reviews and identified research gap, one can optimize the SMA welding process to

- Minimize the welding defects lile porosity, incomplete fusion, holes, incomplete penetration and spatter,
- Reduce the repairing cost,
- Reduce wiewlding time
- Maximize the welding surface quality (weld profile) and productivity.

# Design and Development of an Extruder Assembly to Enhance the Performance of a Plastic 3D Printer

Rugved Hattekar¹, Prem Sagar², P.R. Potdar³, N.J. Panaskar⁴

^{1, 3, 4}Department of Mechanical Engineering, MCT's RGIT Mumbai, Maharashtra, India

²Banaao Makers's Playground Gurugram, Haryana, India

**Abstract:** The digitization and advancement in technology increase the application of 3D printer for prototyping. The practitioners and researches needs a solution to enhance the performance of 3D printer. To design and develop an extruder assembly for performance enhancement of 3D printer. Identify the different needs from practitioners. Identify different alternatives to satisfy needs. Select the best alternative and develop the model. Validate the design through prototype. Enhance the performance of 3D printer by using extruder assembly. The assembly is easy to mount and operate. The 3D printer can be used as chocolate printer by mounting developed extruder assembly. The solution is cost effective with respect to functionality. Increase the functionality of 3D printer and motivates practitioners to take new challenges.

**Keywords:** Brainstorming, Delphi method, plastic 3D printer, Ansys16.0

## 1. INTRODUCTION

The concept of 3D printing started with stereo-lithography. Charles Hull (Hull, 1986) filed a patent for stereo-lithography. The process of stereo-lithography was started by using the principles of additive manufacturing. Eventually over the years, stereo-lithography was developed in different types and one of its forms is 3D printing. In, recent years 3D printers have become cheaper to produce; several models are now available for sale, as well as designs for products. Experts predict 3D printers will be common in homes in coming years (Campbell et al., 2011; Rayna and Striukova, 2016; Shewbridge et al., 2014). 3D printers are not only used to print plastic materials but also to print food like chocolate etc.(Godoi et al., 2016; Li et al., 2014; Sun et al., 2015). The major challenge is separate 3D printers are needed to print chocolate and plastic. In today's era of technology plastic 3D printers are widely used for prototyping, which are not useful for chocolate printing. Therefore, small scale chocolate printing is still a dream for many, who own plastic extrusion 3D printers. There is need to give solution to overcome the difficulty of buying a new machine altogether.

## 2. PROBLEM SELECTION

In this section of paper, different projects were identified related to 3D printing as shown in Table 1.

**TABLE 1: List of projects related to 3D printer**

Project Code	Project description
P1	Select most efficient plastic for 3D printing (Abs, Pla, PLC)
P2	Design and develop extruder assembly to print chocolate.

P3	Identify different factors to reduce print waste.
----	---------------------------------------------------

The Delphi method (Dalkey and Helmer, 1963; Linstone et al., 1975; Okoli and Pawlowski, 2004) was used to select most critical project. The panel of 16 experts was selected to perform Delphi method. The detail of experts is as shown in Table 2. In first round of Delphi method the different projects were discussed and finalized the criteria to rank the projects along with the weights of each criterion. In the second round of Delphi method the expert's opinion were collected and analyzed. The result of Delphi method is as shown in Table 3. The Delphi method suggested design and development extruder assembly to print chocolate is most critical project.

**TABLE 2: Details of expert panel**
